### Binary Search Trees

5/29/2003

(c) 2001-3, University of Washington

21-1

### Costliness of *contains*

- Review: in a binary tree, *contains* is  $O(N)$
- *contains* may be a frequent operation in an application
- Can we do better than  $O(N)$ ?
- Turn to list searching for inspiration...
  - Why was binary search so much better than linear search?
  - Can we apply the same idea to trees?

5/29/2003

(c) 2001-3, University of Washington

21-2

### Binary Search Trees

- Idea: order the nodes in the tree so that, given that a node contains a value  $v$ ,
  - All nodes in its left subtree contain values  $\leq v$
  - All nodes in its right subtree contain values  $\geq v$
- A binary tree with these properties is called a *binary search tree* (BST)
- Notes:
  - Can also define a BST using  $>$  and  $<$  instead of  $\geq$ ,  $\leq$   
This implies there are no duplicate values in the tree
  - In Java, if the values are not primitive types, they must implement interface *comparable* (i.e., provide *compareTo*)

5/29/2003

(c) 2001-3, University of Washington

21-3

### Examples(?)

- Are these are binary search trees? Why or why not?

5/29/2003

(c) 2001-3, University of Washington

21-4

### Implementing a Set with a BST

- Can exploit properties of BSTs to have fast, divide-and-conquer implementations of Set's add and contains operations
  - TreeSet!
- A TreeSet can be represented by a pointer to the root node of a binary search tree, or null if no elements yet

```
public class SimpleTreeSet implements Set {  
    private BTreeNode root; // root node, or null if none  
    public SimpleTreeSet() { root = null; }  
    // size as for BinTree  
    ...  
}
```

5/29/2003

(c) 2001-3, University of Washington

21-5

### *contains* for a BST

- For a general binary tree, *contains* had to search both subtrees
  - Like linear search
- With BSTs, need to only search one subtree!
  - All small elements to the left, all large elements to the right
  - Search either left or right subtree, based on comparison between elem and value at root of tree
  - Like binary search

5/29/2003

(c) 2001-3, University of Washington

21-6

### Code for *contains* (in TreeSet)

```

/** Return whether elem is in set */
public boolean contains(Object elem) {
    return subtreeContains(root, (Comparable)elem);
}
// Return whether elem is in (sub-)tree with root r
private boolean subtreeContains(BTNode r, Comparable elem) {
    if (r == null) {
        return false;
    } else {
        int comp = elem.compareTo(r.item);
        if (comp == 0) { return true; } // found it!
        else if (comp < 0) { return subtreeContains(r.left, elem); } // search left
        else { return subtreeContains(r.right, elem); } // search right
    }
}

```

5/29/2003

(c) 2001-3, University of Washington

21-7

### Examples

contains(6)

contains(10)

5/29/2003

(c) 2001-3, University of Washington

21-8

### Cost of BST *contains*

- Work done at each node:
- Number of nodes visited (depth of recursion):
- Total cost:

5/29/2003

(c) 2001-3, University of Washington

21-9

### *add*

- Must preserve BST invariant: insert new element in correct place in BST
- Two base cases
  - Tree is empty: create new node which becomes the root of the tree
  - If node contains the value, found it; suppress duplicate add
- Recursive case
  - Compare value to current node's value
  - If value < current node's value, add to left subtree recursively
  - Otherwise, add to right subtree recursively

5/29/2003

(c) 2001-3, University of Washington

21-10

### Example

- Add 8, 10, 5, 1, 7, 11 to an initially empty BST, in that order:

5/29/2003

(c) 2001-3, University of Washington

21-11

### Example (2)

- What if we change the order in which the numbers are added?
- Add 1, 5, 7, 8, 10, 11 to a BST, in that order (following the algorithm):

5/29/2003

(c) 2001-3, University of Washington

21-12

### Code for *add* (in TreeSet)

```
/* Ensure that elem is in the set. Return true if elem was added, false otherwise. */
public boolean add(Object elem) {
    try {
        root = addToSubtree(root, (Comparable)elem); // add elem to tree
        return true; // return true (tree changed)
    } catch (DuplicateAdded e) {
        // detected a duplicate addition
        return false; // return false (tree unchanged)
    }
}
/* Add elem to tree rooted at r. Return (possibly new) tree containing elem, or throw
DuplicateAdded if elem already was in tree */
private BTreeNode addToSubtree(BTreeNode r, Comparable elem) throws DuplicateAdded {
    ...
}
```

5/29/2003

(c) 2001-3, University of Washington

21-13

### Code for *addToSubtree*

```
/* Add elem to tree rooted at r. Return (possibly new) tree containing elem, or
throw DuplicateAdded if elem already was in tree */
private BTreeNode addToSubtree(BTreeNode r, Comparable elem) throws
DuplicateAdded {
    if (n == null) { return new BTreeNode(elem, null, null); } // adding to
empty tree
    int comp = elem.compareTo(r.item);
    if (comp == 0) { throw new DuplicateAdded(); } // elem already in tree
    if (comp < 0) { // add to left subtree
        r.left = addToSubtree(r.left, elem);
    } else if (comp > 0) { // add to right subtree
        r.right = addToSubtree(r.right, elem);
    }
    return r; // this tree has been modified to contain elem
}
```

5/29/2003

(c) 2001-3, University of Washington

21-14

### Cost of *add*

- Cost at each node:
- How many recursive calls?
  - Proportional to height of tree
- Best case?
- Worst case?

5/29/2003

(c) 2001-3, University of Washington

21-15

### A Challenge: iterator

- How to return an iterator that traverses the sorted set in order?
  - Need to iterate through the items in the BST, from smallest to largest
- Problem: how to keep track of position in tree where iteration is currently suspended
  - Need to be able to implement next(), which advances to the correct next node in the tree
- Solution: keep track of a path from the root to the current node
  - Still some tricky code to find the correct next node in the tree

5/29/2003

(c) 2001-3, University of Washington

21-16

### Another Challenge: *remove*

- Algorithm: find the node containing the element value being removed, and remove that node from the tree
- Removing a leaf node is easy: replace with an empty tree
- Removing a node with only one non-empty subtree is easy: replace with that subtree
- How to remove a node that has two non-empty subtrees?
  - Need to pick a new element to be the new root node, and adjust at least one of the subtrees
  - E.g., remove the largest element of the left subtree (will be one of the easy cases described above), make that the new root

5/29/2003

(c) 2001-3, University of Washington

21-17

### Analysis of Binary Search Tree Operations

- Cost of operations is proportional to height of tree
- Best case: tree is *balanced*
  - Depth of all leaf nodes is roughly the same
  - Height of a balanced tree with  $n$  nodes is  $\sim \log_2 n$
- If tree is unbalanced, height can be as bad as the number of nodes in the tree
  - Tree becomes just a linear list

5/29/2003

(c) 2001-3, University of Washington

21-18

## Summary

---

- A binary search tree is a good general implementation of a set, if the elements can be ordered
  - Both contains and add benefit from divide-and-conquer strategy
  - No sliding needed for add
  - Good properties depend on the tree being roughly balanced
- Open issues (or, why take a data structures course?)
  - How are other operations implemented (e.g. iterator, remove)?
  - Can you keep the tree balanced as items are added and removed?
