Binary Search Trees

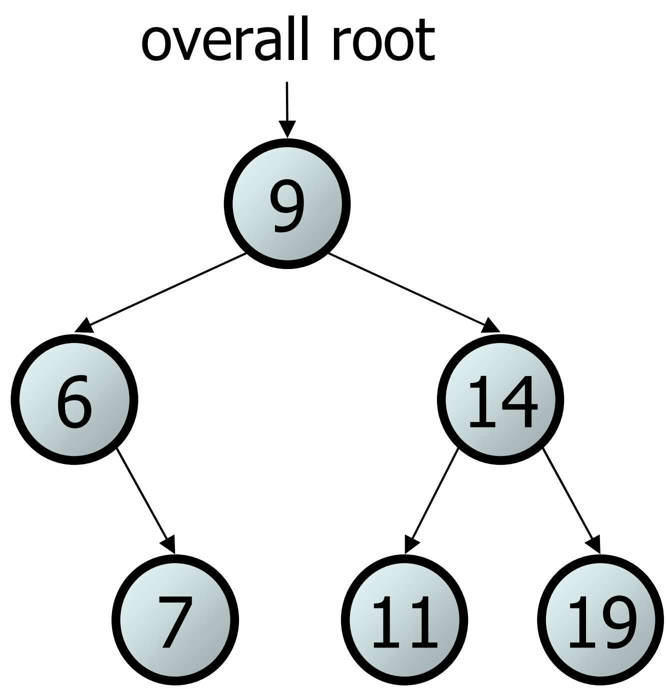
read 17.3

slides created by Marty Stepp
http://www.cs.washington.edu/143/

Exercise

- Add a method named `printSideways` to the `IntTree` class that prints the tree in a sideways indented format, with right nodes above roots above left nodes, with each level 4 spaces more indented than the one above it.
  - Example: Output from the tree below:

```
        19
    14
        11
9
        7
    6
```



Exercise solution

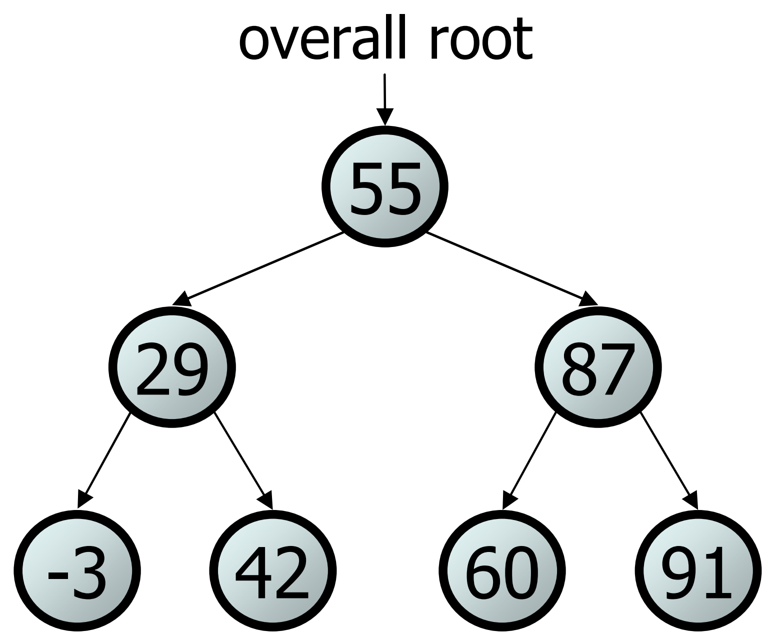
```
// Prints the tree in a sideways indented format.
public void printSideways() {
    printSideways(overallRoot, "");
}

private void printSideways(IntTreeNode root,
                           String indent) {
    if (root != null) {
        printSideways(root.right, indent + "    ");
        System.out.println(indent + root.data);
        printSideways(root.left, indent + "    ");
    }
}
```

Binary search trees

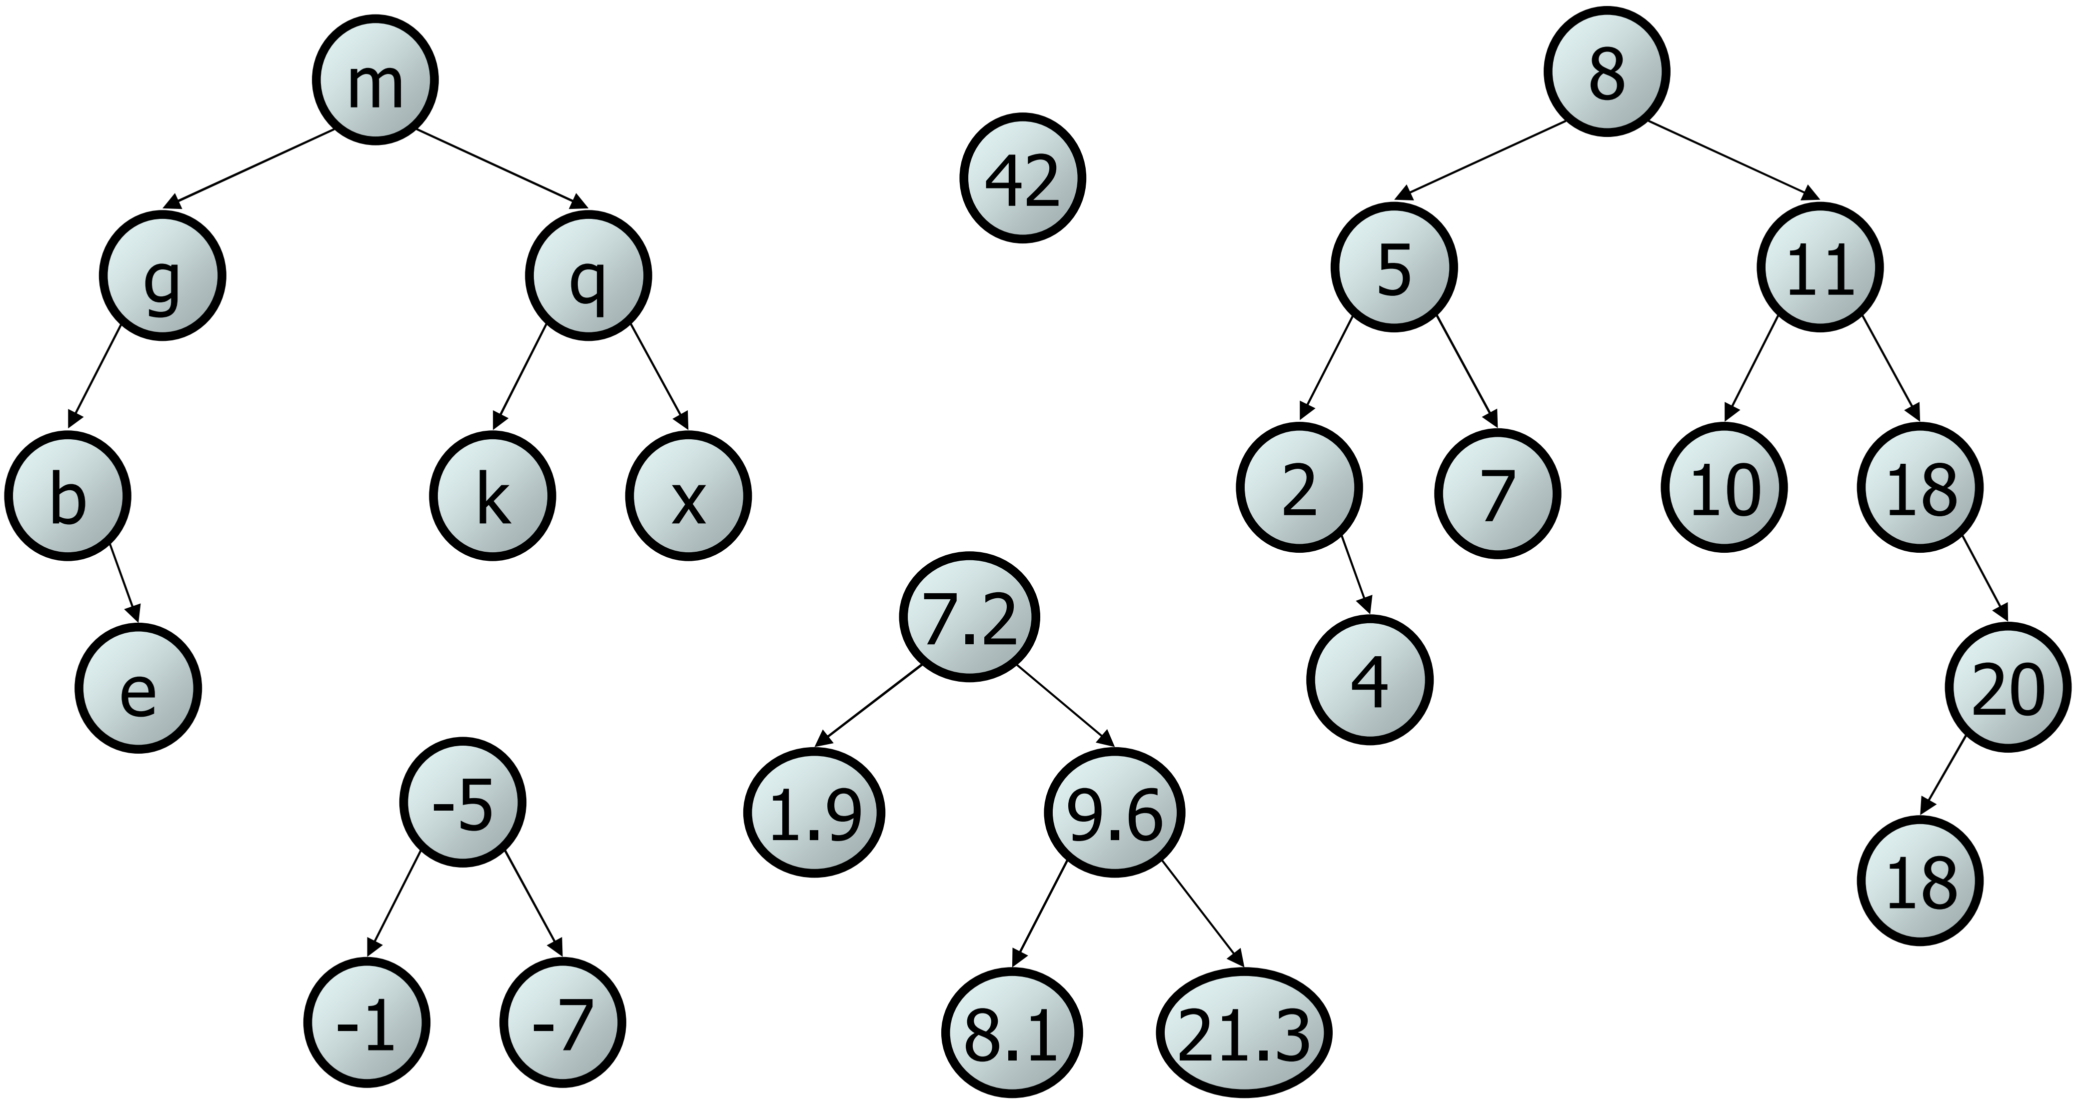
- **binary search tree** ("BST"): a binary tree that is either:
  - empty (`null`), or
  - a root node R such that:
    - every element of R's left subtree contains data "less than" R's data,
    - every element of R's right subtree contains data "greater than" R's,
    - R's left and right subtrees are also binary search trees.

- BSTs store their elements in sorted order, which is helpful for searching/sorting tasks.



Exercise

- Which of the trees shown are legal binary search trees?

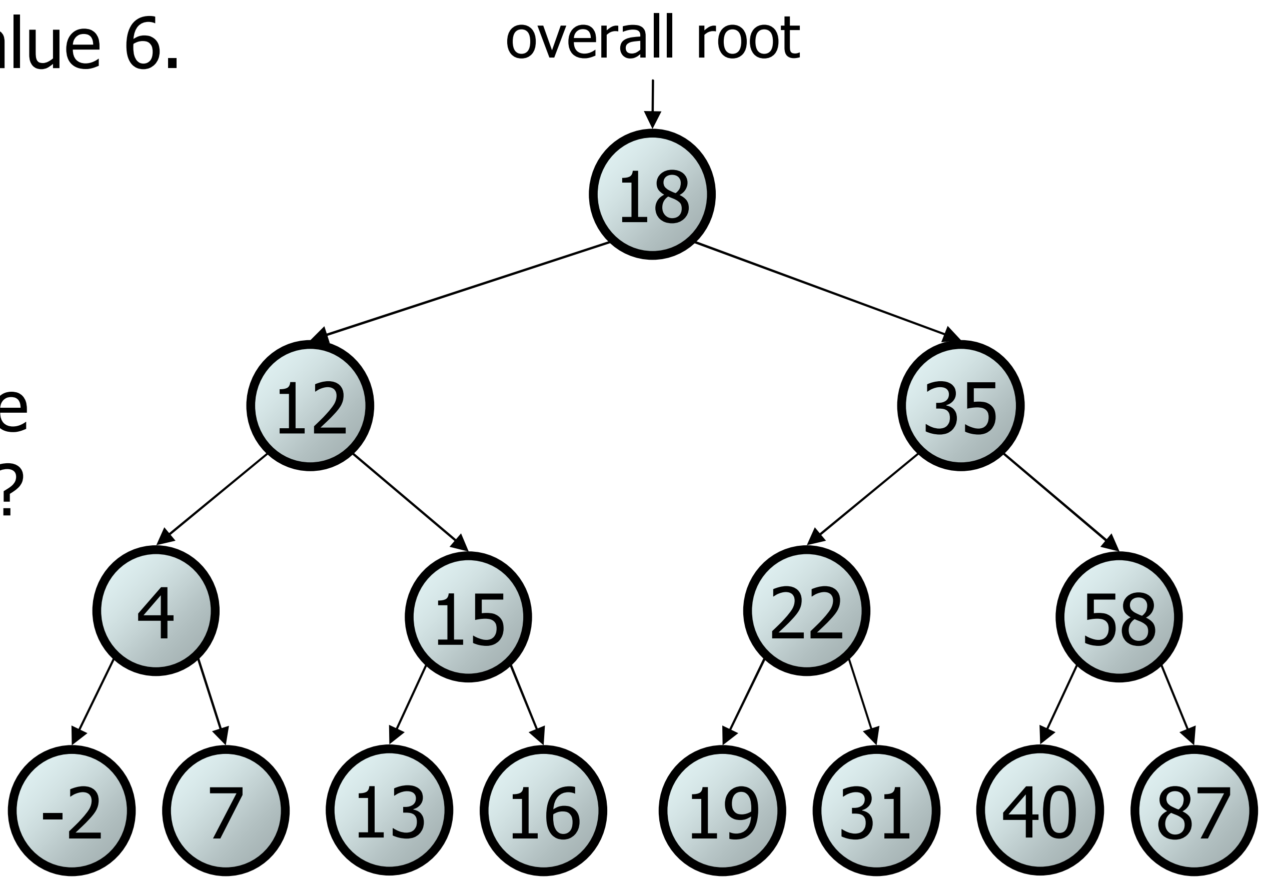


Searching a BST

- Describe an algorithm for searching the tree below for the value 31.

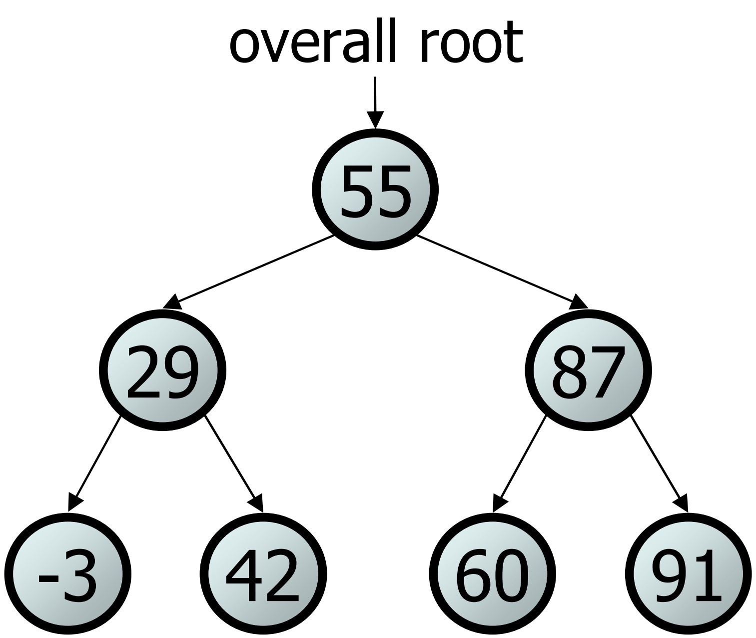
- Then search for the value 6.

- What is the maximum number of nodes you would need to examine to perform any search?



Exercise

- Add a method `contains` to the `IntTree` class that searches the tree for a given integer, returning `true` if it is found in the tree and `false` if not. Assume that the elements of the tree constitute a legal binary search tree.
  - If an `IntTree` variable `tree` referred to the tree below, the following calls would have the following results:
    - `tree.contains(29)` → `true`
    - `tree.contains(55)` → `true`
    - `tree.contains(63)` → `false`
    - `tree.contains(35)` → `false`



Exercise solution

```
// Returns whether this tree contains the given integer.
public boolean contains(int value) {
    return contains(overallRoot, value);
}

private boolean contains(IntTreeNode root, int value) {
    if (root == null) {
        return false;
    } else if (root.data == value) {
        return true;
    } else if (root.data > value) {
        return contains(root.left, value);
    } else {   // root.data < value
        return contains(root.right, value);
    }
}
```

Adding to a BST

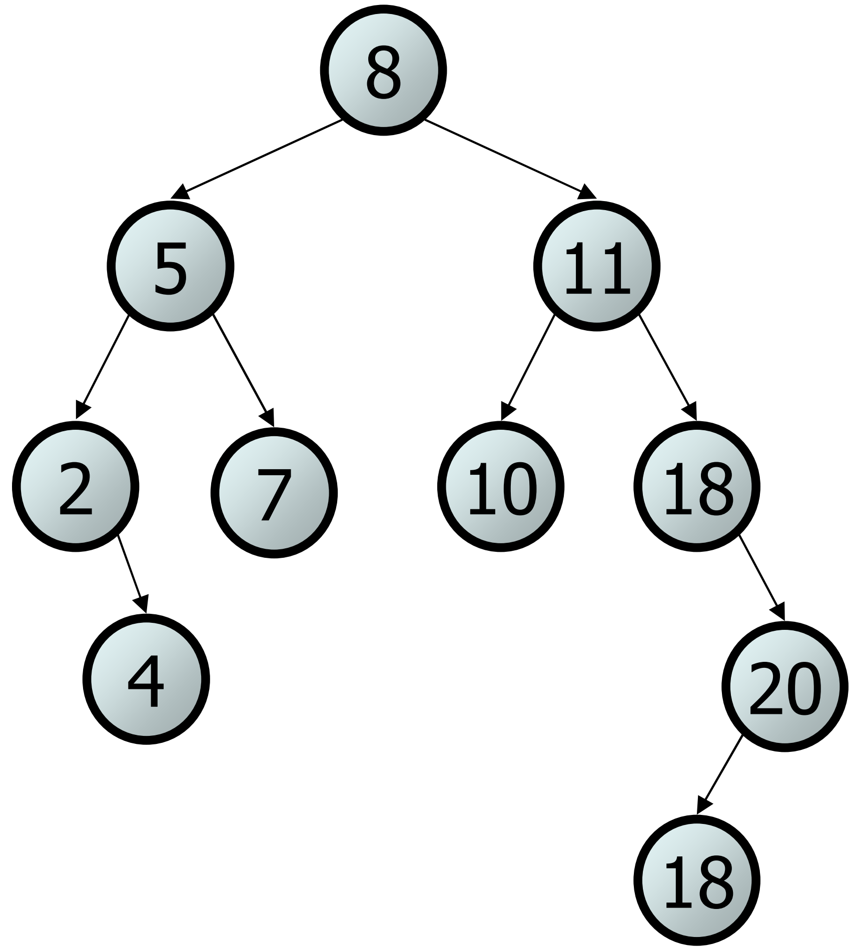
- Suppose we want to add the value 14 to the BST below.
  - Where should the new node be added?

- Where would we add the value 3?

- Where would we add 7?

- If the tree is empty, where should a new value be added?

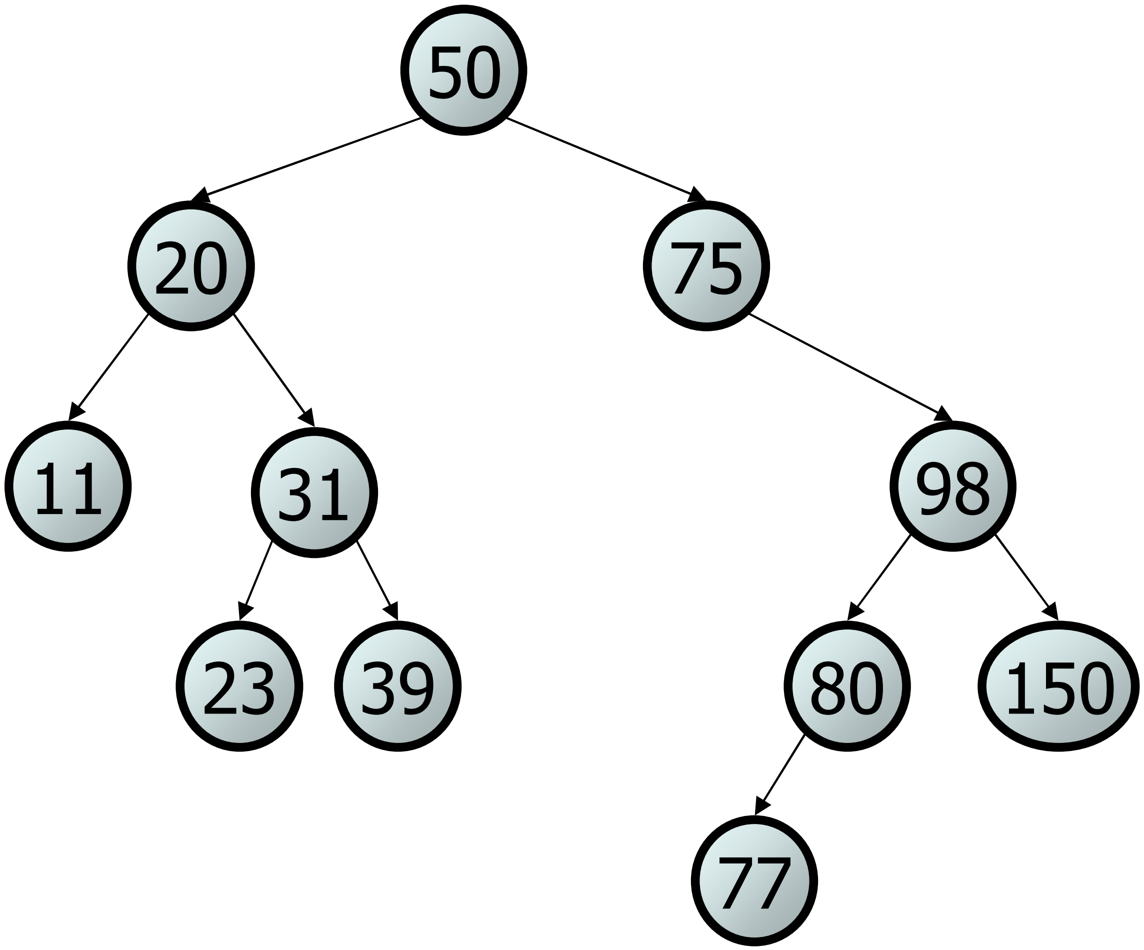
- What is the general algorithm?



Adding exercise

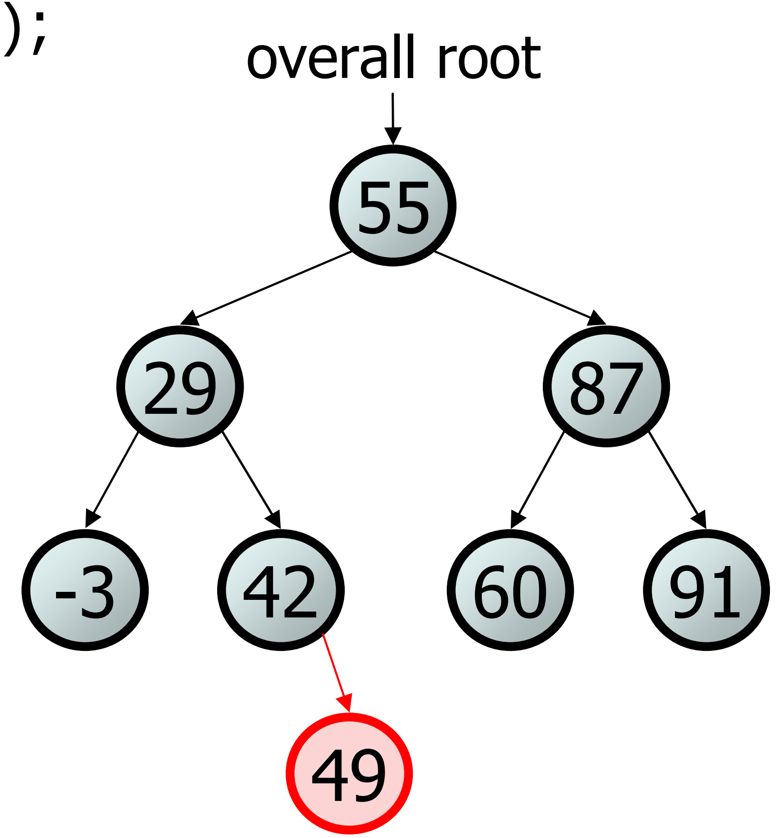
- Draw what a binary search tree would look like if the following values were added to an initially empty tree in this order:

50
20
75
98
80
31
150
39
23
11
77



Exercise

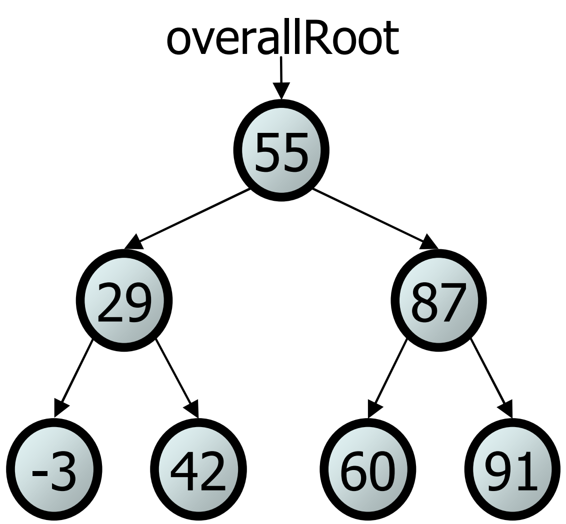
- Add a method `add` to the `IntTree` class that adds a given integer value to the tree. Assume that the elements of the `IntTree` constitute a legal binary search tree, and add the new value in the appropriate place to maintain ordering.
  - `tree.add(49);`



An incorrect solution

```
// Adds the given value to this BST in sorted order.
public void add(int value) {
    add(overallRoot, value);
}

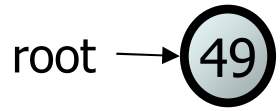
private void add(IntTreeNode root, int value) {
    if (root == null) {
        root = new IntTreeNode(value);
    } else if (root.data > value) {
        add(root.left, value);
    } else if (root.data < value) {
        add(root.right, value);
    }
    // else root.data == value;
    // a duplicate (don't add)
}
```



- Why doesn't this solution work?

The problem

- Much like with linked lists, if we just modify what a local variable refers to, it won't change the collection.



```
private void add(IntTreeNode root, int value) {
    if (root == null) {
        root = new IntTreeNode(value);
```

  - In the linked list case, how did we correct this problem? How did we actually modify the list?

x = change(x);

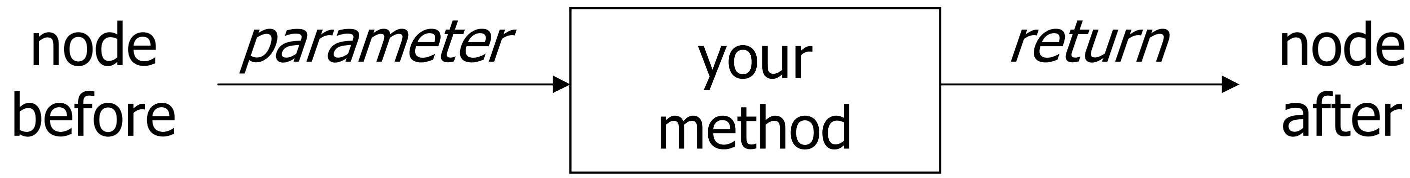
- All String object methods that modify a String actually return a new String object.
  - If we want to modify a string variable, we must re-assign it.

```
String s = "lil bow wow";
s.toUpperCase();
System.out.println(s);    // lil bow wow
s = s.toUpperCase();
System.out.println(s);    // LIL BOW WOW
```

  - We call this general algorithmic pattern **x = change(x);**
  - We will use this approach when writing methods that modify the structure of a binary tree.

Applying x = change(x)

- Methods that modify a tree should have the following pattern:
  - input (parameter): old state of the node
  - output (return): new state of the node



- In order to actually change the tree, you must reassign:

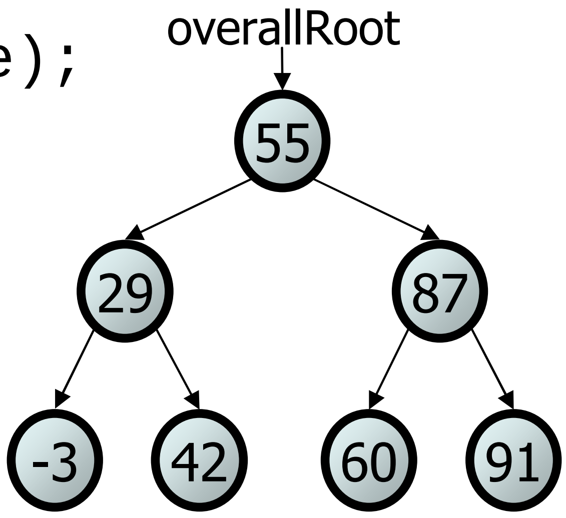
```
root = change(root, parameters);
root.left = change(root.left, parameters);
root.right = change(root.right, parameters);
```

A correct solution

```
// Adds the given value to this BST in sorted order.
public void add(int value) {
    overallRoot = add(overallRoot, value);
}

private IntTreeNode add(IntTreeNode root, int value) {
    if (root == null) {
        root = new IntTreeNode(value);
    } else if (root.data > value) {
        root.left = add(root.left, value);
    } else if (root.data < value) {
        root.right = add(root.right, value);
    } // else a duplicate

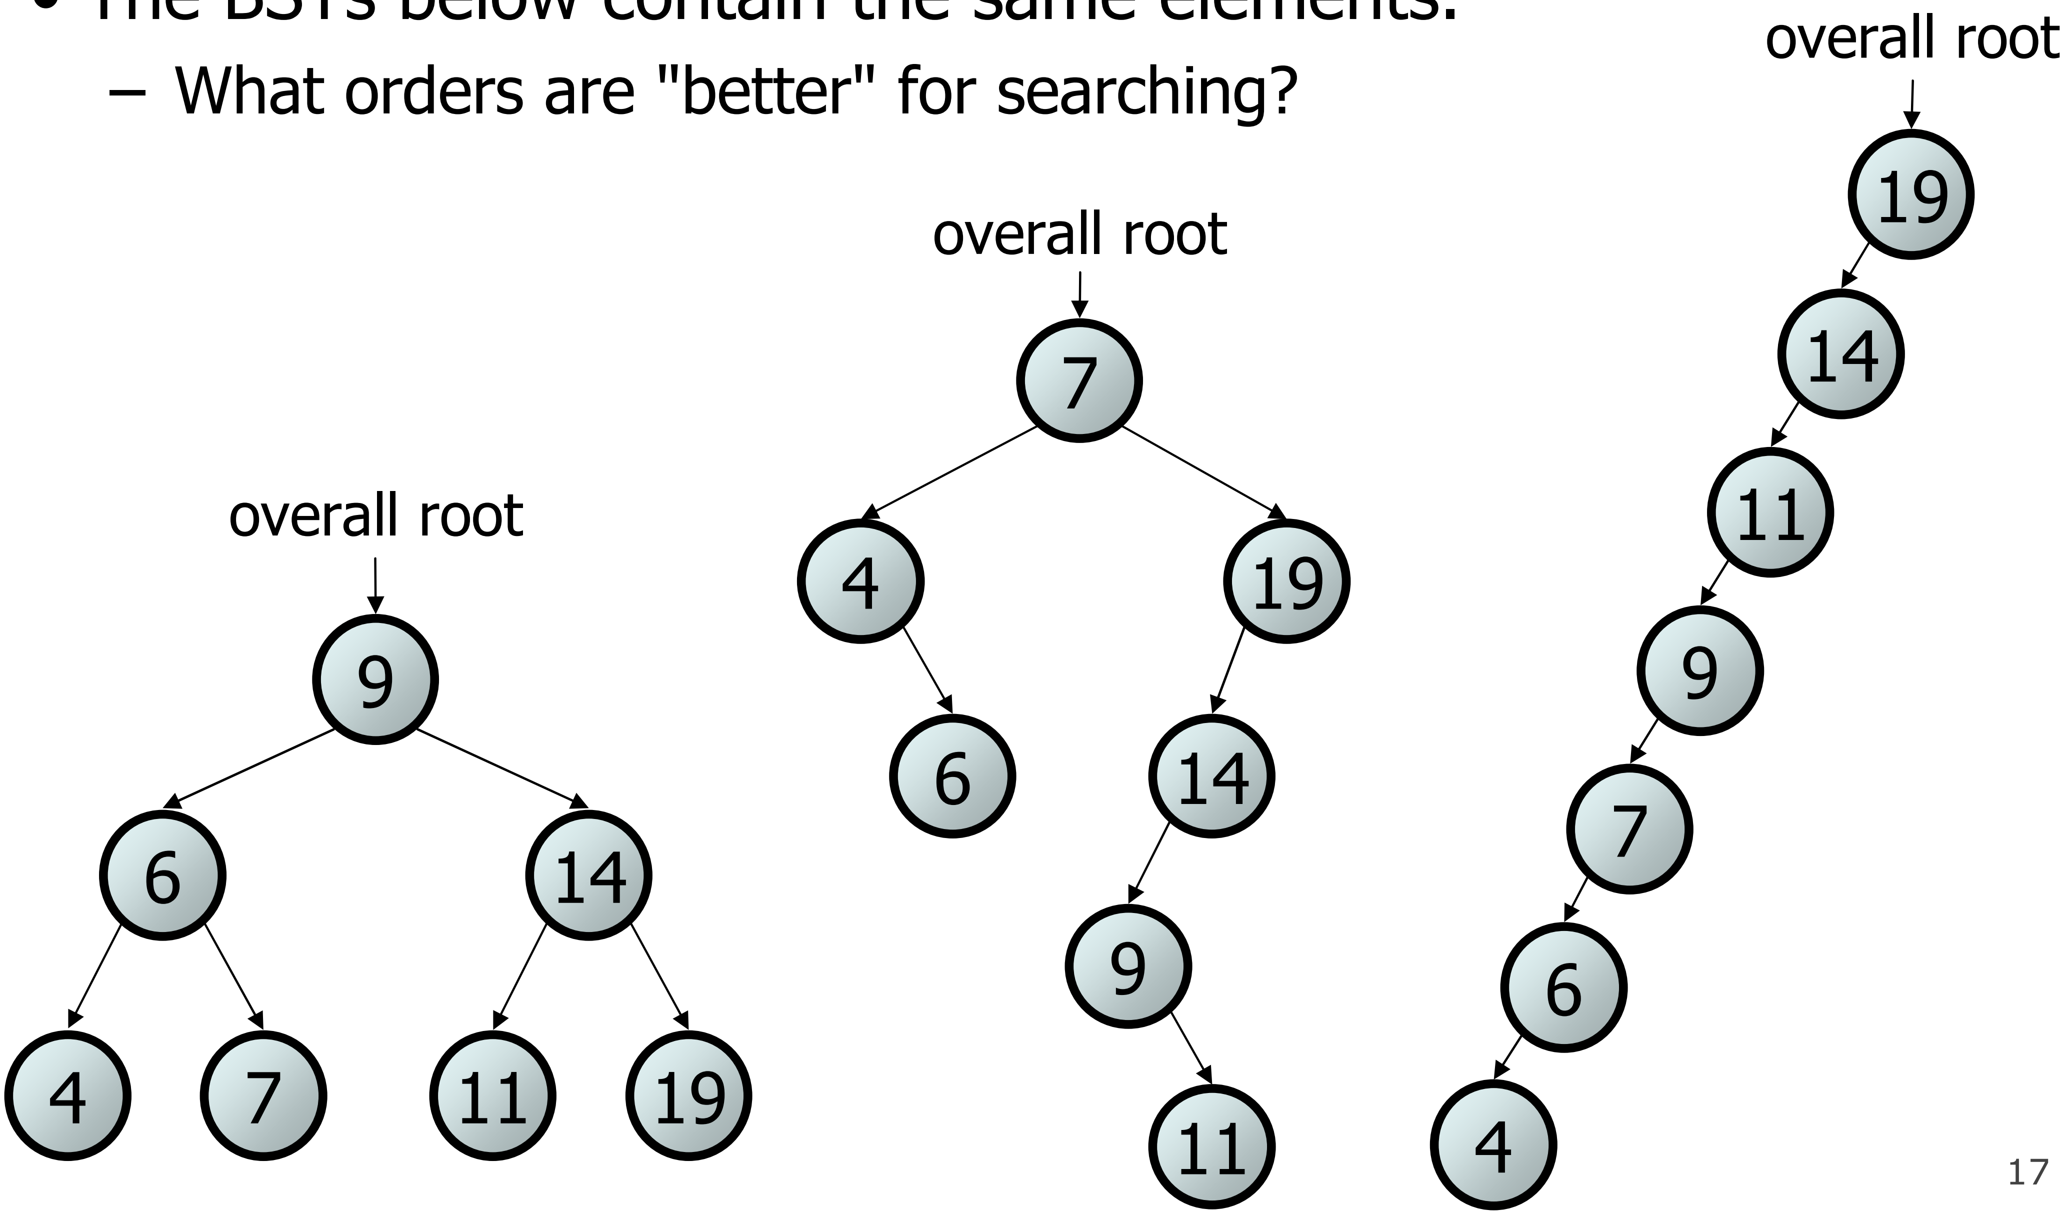
    return root;
}
```



- Think about the case when `root` is a leaf...

Searching BSTs

- The BSTs below contain the same elements.
  - What orders are "better" for searching?



Trees and balance

- **balanced tree**: One whose subtrees differ in height by at most 1 and are themselves balanced.
  - A balanced tree of N nodes has a height of ~ $\log_2$ N.
  - A very unbalanced tree can have a height close to N.

  - The runtime of adding to / searching a BST is closely related to height.
  - Some tree collections (e.g. `TreeSet`) contain code to balance themselves as new nodes are added.
