## Arrays (review)

slides created by Marty Stepp

<http://www.cs.washington.edu/143/>

# Arrays (7.1)

- **array**: An object that stores many values of the same type.
    - **element**: One value in an array.
    - **index**: A 0-based integer to access an element from an array.

# Array declaration

```
type [ ] name = new type [length] ;
```

- Example:

```
int [ ] numbers = new int [10] ;
```

- All elements' values are initially 0.

<i>index</i>	0	1	2	3	4	5	6	7	8	9
<i>value</i>	0	0	0	0	0	0	0	0	0	0

# Accessing elements

```
name [index]           // access  
name [index] = value; // modify
```

- Example:

```
numbers[0] = 27;  
numbers[3] = -6;
```

```
System.out.println(numbers[0]);  
if (numbers[3] < 0) {  
    System.out.println("value 3 is negative");  
}
```

<i>index</i>	0	1	2	3	4	5	6	7	8	9
<i>value</i>	27	0	0	-6	0	0	0	0	0	0

# Out-of-bounds

- Legal indexes: between **0** and the **array's length - 1**.
  - Reading or writing any index outside this range will throw an `ArrayIndexOutOfBoundsException`.
- Example:

```
int[] data = new int[10];
System.out.println(data[0]);          // okay
System.out.println(data[9]);          // okay
System.out.println(data[-1]);        // exception
System.out.println(data[10]);        // exception
```

<i>index</i>	0	1	2	3	4	5	6	7	8	9
<i>value</i>	0	0	0	0	0	0	0	0	0	0

# The length field

**name.length**

- An array's **length** field stores its number of elements.

```
for (int i = 0; i < numbers.length; i++) {  
    System.out.print(numbers[i] + " ");  
}  
// output: 0 2 4 6 8 10 12 14
```

- It does not use parentheses like a String's `.length()`.

# Quick initialization

```
type [ ] name = { value, value, ... value } ;
```

- Example:

```
int [ ] numbers = { 12, 49, -2, 26, 5, 17, -6 } ;
```

<i>index</i>	0	1	2	3	4	5	6
<i>value</i>	12	49	-2	26	5	17	-6

- Useful when you know what the array's elements will be.
- The compiler figures out the size by counting the values.

# The Arrays class

- Class `Arrays` in package `java.util` has useful static methods for manipulating arrays:

Method name	Description
<code>binarySearch(<b>array</b>, <b>value</b>)</code>	returns the index of the given value in a <u>sorted</u> array (< 0 if not found)
<code>copyOf(<b>array</b>, <b>length</b>)</code>	returns a new array with same elements
<code>equals(<b>array1</b>, <b>array2</b>)</code>	returns <code>true</code> if the two arrays contain the same elements in the same order
<code>fill(<b>array</b>, <b>value</b>)</code>	sets every element in the array to have the given value
<code>sort(<b>array</b>)</code>	arranges the elements in the array into ascending order
<code>toString(<b>array</b>)</code>	returns a string representing the array, such as "[10, 30, 17]"

# Array as parameter

```
public static type methodName(type [ ] name) {
```

- Example:

```
public static double average(int [ ] numbers) {  
    ...  
}
```

- Call:

**methodName**(**arrayName**) ;

- Example:

```
int [ ] scores = {13, 17, 12, 15, 11};  
double avg = average(scores);
```

# Array as return

```
public static type [] methodName(parameters) {
```

- Example:

```
public static int [] countDigits(int n) {  
    int [] counts = new int[10];  
    ...  
    return counts;  
}
```

- Call:

```
type [] name = methodName(parameters);
```

- Example:

```
int [] tally = countDigits(229231007);  
System.out.println(Arrays.toString(tally));
```

# Exercise

- Write a method named `stutter` that accepts an array of integers as a parameter and returns a new array, twice as long as the original, with two copies of each original element.

- If the method were called in the following way:

```
int[] a = {4, 7, -2, 0, 15};  
int[] a2 = stutter(a);  
System.out.println("a is " + Arrays.toString(a));  
System.out.println("a2 is " + Arrays.toString(a2));
```

- The output produced would be:

```
a is [4, 7, -2, 0, 15]  
a2 is [4, 4, 7, 7, -2, -2, 0, 0, 15, 15]
```

# Exercise solutions

```
public static int[] stutter(int[] a) {  
    int[] result = new int[a.length * 2];  
    for (int i = 0; i < a.length; i++) {  
        result[2 * i] = a[i];  
        result[2 * i + 1] = a[i];  
    }  
    return result;  
}  
  
public static int[] stutter(int[] a) {  
    int[] result = new int[a.length * 2];  
    for (int i = 0; i < result.length; i++) {  
        result[i] = a[i / 2];  
    }  
    return result;  
}
```

# Testing code (bonus)

- Q: How can we tell if our `stutter` method works properly?
  - A: We must test it.
- Q: How do we test code?
  - A: Call the method several times and print/examine the results.
- Q: Can we test all possible usages of this method?  
Q: Can we prove that the `stutter` code has no bugs?
  - A: No; exhaustive testing is impractical/impossible for most code.
  - A: No; testing finds bugs but cannot prove the absence of bugs.

# How to test code

- **test case:** Running a piece of code once on a given input.
- Q: Which cases should we choose to test?
  - *equivalence classes of input*: Think about kinds of inputs:
    - positive vs. negative numbers vs. 0; null (maybe)
    - unique values vs. duplicates (consecutive and non-consecutive)
    - an empty array; a 1-element array; a many-element array
- Q: What are some properties to look for in testing code?
  - *boundaries*: Hits cases close to a relevant boundary, e.g. the maximum allowed value, the first/last element in an array, etc.
  - *code coverage*: Hits all paths through code (`if/else`s, etc.)
  - *preconditions*: What does the method assume? Does the code ever violate those assumptions?

# Exercise

- Write a short piece of code that tests the `stutter` method.
  - Decide on a group of test input cases.
  - For each test case:
    - Print the array's contents before and after stuttering.
    - Print whether the test was successful or failed.

# Exercise solution 1

```
public static void main(String[] args) {  
    int[] a1 = {1, 2, 4, 5, 6};  
    int[] a2 = stutter(a1);  
    System.out.println(Arrays.toString(a2));  
    ...  
}
```

- Pros:
  - simple, short
- Cons:
  - must manually check output to see if it is correct
  - must copy/paste to create each test case (redundant)

# Exercise solution 2

```
public static void main(String[] args) {  
    test(new int[] {1, 2, 4, 5, 6, 8},  
          new int[] {1, 1, 2, 2, 4, 4, 5, 5, 6, 6, 8, 8});  
    test(new int[] {0, 0, 7, 9},  
          new int[] {0, 0, 0, 0, 7, 7, 9, 9});  
    test(new int[] {-50, 95, -9876},  
          new int[] {-50, -50, 95, 95, -9876, -9876});  
    test(new int[] {42}, new int[] {42, 42});  
    test(new int[] {}, new int[] {});  
}
```

```
public static void test(int[] a, int[] expected) {  
    int[] a2 = stutter(a);  
    System.out.print((Arrays.toString(a) + " -> " +  
                      Arrays.toString(a2) + " : " );  
    if (Arrays.equals(a2, expected)) {  
        System.out.println("Pass");  
    } else {  
        System.out.println("FAIL!!!!");  
    }  
}
```
