CSE 143
Lecture 22

Priority Queues; Huffman Encoding

slides created by Marty Stepp, Hélène Martin, and Daniel Otero
http://www.cs.washington.edu/143/
Prioritization problems

• **print jobs:** The CSE lab printers constantly accept and complete jobs from all over the building. Suppose we want them to print faculty jobs before staff before student jobs, and grad students before undergraduate students, etc.?

• **ER scheduling:** You are in charge of scheduling patients for treatment in the ER. A gunshot victim should probably get treatment sooner than that one guy with a sore neck, regardless of arrival time. How do we always choose the most urgent case when new patients continue to arrive?

• *Why can't we solve these problems efficiently with the data structures we have (list, sorted list, map, set, BST, etc.)*?
Some poor choices

- **list**: store jobs in a list; remove min/max by searching \(O(N)\)
  - problem: expensive to search

- **sorted list**: store in sorted list; binary search it in \(O(\log N)\) time
  - problem: expensive to add/remove \(O(M)\)

- **binary search tree**: store in BST, go right for max in \(O(\log N)\)
  - problem: tree becomes unbalanced
Priority queue ADT

- **priority queue**: a collection of ordered elements that provides fast access to the minimum (or maximum) element
  - usually implemented using a tree structure called a *heap*

- **priority queue operations**:
  - **add**: adds in order; O(log \(N\)) worst
  - **peek**: returns **minimum** value; O(1) always
  - **remove**: removes/returns **minimum** value; O(log \(N\)) worst
  - **isEmpty**, **clear**, **size**, **iterator**: O(1) always
Java's PriorityQueue class

```java
class PriorityQueue<E> implements Queue<E>
```

<table>
<thead>
<tr>
<th>Method/Constructor</th>
<th>Description</th>
<th>Runtime</th>
</tr>
</thead>
<tbody>
<tr>
<td>PriorityQueue&lt;E&gt;()</td>
<td>constructs new empty queue</td>
<td>O(1)</td>
</tr>
<tr>
<td>add(E value)</td>
<td>adds value in sorted order</td>
<td>O(log N)</td>
</tr>
<tr>
<td>clear()</td>
<td>removes all elements</td>
<td>O(1)</td>
</tr>
<tr>
<td>iterator()</td>
<td>returns iterator over elements</td>
<td>O(1)</td>
</tr>
<tr>
<td>peek()</td>
<td>returns minimum element</td>
<td>O(1)</td>
</tr>
<tr>
<td>remove()</td>
<td>removes/returns min element</td>
<td>O(log N)</td>
</tr>
<tr>
<td>size()</td>
<td>number of elements in queue</td>
<td>O(1)</td>
</tr>
</tbody>
</table>

```java
Queue<String> pq = new PriorityQueue<String>();
pq.add("Helene");
pq.add("Marty");
...```
Inside a priority queue

- Usually implemented as a **heap**, a kind of binary tree.
- Instead of sorted left → right, it's sorted top → bottom
  - guarantee: each child is greater (lower priority) than its ancestors
  - add/remove causes elements to "bubble" up/down the tree
  - (take CSE 332 or 373 to learn about implementing heaps!)
Exercise: Fire the TAs

• We have decided that TA performance is unacceptably low.
  – Write a class FiringSquad that reads a list of TAs from a file.
  – Find all with \( \leq 2 \) quarters experience, and fire/replace them.
  – Print the final list of TAs to the console, sorted by experience.

  – Input format:
    
    name  quarters
    Zack  0
    Sara  4
    Tyler 2
Priority queue ordering

• For a priority queue to work, elements must have an ordering
  – in Java, this means implementing the `Comparable` interface

• Reminder:

```java
public class Foo implements Comparable<Foo> {
    ...
    public int compareTo(Foo other) {
        // Return positive, zero, or negative integer
    }
}
```
Homework 8
(Huffman Coding)
File compression

• **compression**: Process of encoding information in fewer bits.
  – But isn't disk space cheap?

• Compression applies to many things:
  – store photos without exhausting disk space
  – reduce the size of an e-mail attachment
  – make web pages smaller so they load faster
  – reduce media sizes (MP3, DVD, Blu-Ray)
  – make voice calls over a low-bandwidth connection (cell, Skype)

• Common compression programs:
  – WinZip or WinRAR for Windows
  – Stuffit Expander for Mac
**ASCII encoding**

- **ASCII**: Mapping from characters to integers (binary bits).
  - Maps every possible character to a number ( 'A' → 65)
  - uses one *byte* (8 *bits*) for each character
  - most text files on your computer are in ASCII format

<table>
<thead>
<tr>
<th>Char</th>
<th>ASCII value</th>
<th>ASCII (binary)</th>
</tr>
</thead>
<tbody>
<tr>
<td>' '</td>
<td>32</td>
<td>00100000</td>
</tr>
<tr>
<td>'a'</td>
<td>97</td>
<td>01100001</td>
</tr>
<tr>
<td>'b'</td>
<td>98</td>
<td>01100010</td>
</tr>
<tr>
<td>'c'</td>
<td>99</td>
<td>01100011</td>
</tr>
<tr>
<td>'e'</td>
<td>101</td>
<td>01100101</td>
</tr>
<tr>
<td>'z'</td>
<td>122</td>
<td>01111010</td>
</tr>
</tbody>
</table>
Huffman encoding

- **Huffman encoding**: Uses variable lengths for different characters to take advantage of their relative frequencies.
  - Some characters occur more often than others. If those characters use < 8 bits each, the file will be smaller.
  - Other characters need > 8, but that's OK; they're rare.

<table>
<thead>
<tr>
<th>Char</th>
<th>ASCII value</th>
<th>ASCII (binary)</th>
<th>Hypothetical Huffman</th>
</tr>
</thead>
<tbody>
<tr>
<td>' '</td>
<td>32</td>
<td>00100000</td>
<td>10</td>
</tr>
<tr>
<td>'a'</td>
<td>97</td>
<td>01100001</td>
<td>0001</td>
</tr>
<tr>
<td>'b'</td>
<td>98</td>
<td>01100010</td>
<td>01110100</td>
</tr>
<tr>
<td>'c'</td>
<td>99</td>
<td>01100011</td>
<td>001100</td>
</tr>
<tr>
<td>'e'</td>
<td>101</td>
<td>01100101</td>
<td>1100</td>
</tr>
<tr>
<td>'z'</td>
<td>122</td>
<td>01111010</td>
<td>00100011110</td>
</tr>
</tbody>
</table>
Huffman's algorithm

- **The idea:** Create a "Huffman Tree" that will tell us a good binary representation for each character.
  - Left means 0, right means 1.
    - example: 'b' is 10
  - More frequent characters will be "higher" in the tree (have a shorter binary value).

- To build this tree, we must do a few steps first:
  - **Count occurrences** of each unique character in the file.
  - Use a **priority queue** to order them from least to most frequent.
1. **Count** the occurrences of each character in file
   \{ ' ' = 2, 'a' = 3, 'b' = 3, 'c' = 1, EOF = 1 \}

2. Place characters and counts into **priority queue**

3. Use priority queue to create **Huffman tree** →

4. **Traverse** tree to find (char → binary) map
   \{ ' ' = 00, 'a' = 11, 'b' = 10, 'c' = 010, EOF = 011 \}

5. For each char in file, **convert** to compressed binary version
   11 10 00 11 10 00 010 1 1 10 011 0 0
1) Count characters

• **step 1**: count occurrences of characters into a map
  – example input file contents:

    ab ab cab

<table>
<thead>
<tr>
<th>byte</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>char</td>
<td>'a'</td>
<td>'b'</td>
<td>' '</td>
<td>'a'</td>
<td>'b'</td>
<td>' '</td>
<td>'c'</td>
<td>'a'</td>
<td>'b'</td>
<td>EOF</td>
</tr>
<tr>
<td>ASCII</td>
<td>97</td>
<td>98</td>
<td>32</td>
<td>97</td>
<td>98</td>
<td>32</td>
<td>99</td>
<td>97</td>
<td>98</td>
<td>256</td>
</tr>
<tr>
<td>binary</td>
<td>01100001</td>
<td>01100010</td>
<td>00100000</td>
<td>01100001</td>
<td>01100010</td>
<td>00100000</td>
<td>01100011</td>
<td>01100001</td>
<td>01100010</td>
<td>N/A</td>
</tr>
</tbody>
</table>

counts: {' ' = 2, 'a' = 3, 'b' = 3, 'c' = 1, EOF = 1}

– every file actually ends with a single invisible character indicating the end-of-file (**EOF**)

– *(in HW8, we do this part for you)*
2) Create priority queue

- **step 2**: place characters and counts into a priority queue
  - store a single character and its count as a **Huffman node** object
  - the priority queue will organize them into ascending order
3) Build Huffman tree

- **step 2**: create "Huffman tree" from the node counts

  **algorithm:**
  - Put all node counts into a **priority queue**.
  - while P.Q. size > 1:
    - Remove two rarest characters.
    - Combine into a single node with these two as its children.
Build tree example
4) Tree to binary encodings

• The Huffman tree tells you the binary encodings to use.
  – left means 0, right means 1
  – example: 'b' is 10

– What are the binary encodings of:

EOF,
',
'c',
'a'?

– What is the relationship between tree branch height, binary representation length, character frequency, etc.?
5) compress the actual file

- Based on the preceding tree, we have the following encodings:
  \[
  \{ ' ' = 00, 'a' = 11, 'b' = 10, 'c' = 010, \text{EOF} = 011 \}
  \]

- Using this map, we can encode the file into a shorter binary representation. The text \texttt{ab ab cab} would be encoded as:

  \[
  \begin{array}{cccccccccccc}
  \text{char} & 'a' & 'b' & ' ' & 'a' & 'b' & ' ' & 'c' & 'a' & 'b' & \text{EOF} \\
  \text{binary} & 11 & 10 & 00 & 11 & 10 & 00 & 010 & 11 & 10 & 011 \\
  \end{array}
  \]

  \[
  \text{binary } \texttt{1110001110000101110011}, \ (22 \text{ bits}, \sim 3 \text{ bytes})
  \]

- How would we go back in the opposite direction (decompress)?
Decompressing

How do we decompress a file of Huffman-compressed bits?

• useful "prefix property"
  – No encoding A is the prefix of another encoding B
  – I.e. never will have $x \rightarrow 011$ and $y \rightarrow 011100110$

• the algorithm:
  – Read each bit one at a time from the input.
  – If the bit is 0, go left in the tree; if it is 1, go right.
  – If you reach a leaf node, output the character at that leaf and go back to the tree root.
Decompressing

- Use the tree to decompress a compressed file with these bits:

```
1011010001101011011011011
bac aca
```

- Read each bit one at a time.
- If it is 0, go left; if 1, go right.
- If you reach a leaf, output the character there and go back to the tree root.

Output:

```
bac aca
```
Public methods to write

- HuffmanTree(Map<Character, Integer> counts)
  - Given (char → count) map for a file, create Huffman tree (Steps 2-3)

- public Map<Character, String> createEncodings()
  - Traverse Huffman tree to produce (char → binary) mapping (Step 4)

- public void compress(List<Character> in, BitOutputStream out)
  - Use encodings to compress chars in list into given output (Step 5)

- public void decompress(BitInputStream in, PrintStream out)
  - Use Huffman tree to unzip the input into the given output
Bit I/O streams

- Java's input/output streams read/write 1 byte (8 bits) at a time.
  - We want to read/write one single bit at a time.

- **BitInputStream**: Reads one bit at a time from input.

  ```java
  public BitInputStream(InputStream in) {
      // Creates stream to read bits from given input
  }

  public int readBit() {
      // Reads a single 1 or 0; returns -1 at end of file
  }

  public boolean hasNextBit() {
      // Returns true iff another bit can be read
  }

  public void close() {
      // Stops reading from the stream
  }
  ```

- **BitOutputStream**: Writes one bit at a time to output.

  ```java
  public BitOutputStream(OutputStream out) {
      // Creates stream to write bits to given output
  }

  public void writeBit(int bit) {
      // Writes a single bit
  }

  public void writeBits(String bits) {
      // Treats each character of the given string as a bit ('0' or '1') and writes each of those bits to the output
  }

  public void close() {
      // Stops reading from the stream
  }
  ```
