

# **CSE 143**

# **Lecture 4**

**Implementing ArrayIntList; Binary Search**

reading: 15.1 - 15.3

slides adapted from Marty Stepp and Hélène Martin  
<http://www.cs.washington.edu/143/>

# Exercise

- Let's write a class that implements a list using an `int []`
  - We'll call it `ArrayList`
  - its behavior:
    - `add(value)`,
    - `get(index)`,
    - `size()`,
    - `remove(index)`,
    - `indexOf(value)`,
    - `toString()`,
    - ...
  - The list's `size` will be the number of elements added to it so far.
    - The actual array length ("capacity") in the object may be larger. We'll start with an array of **length 10** by default.

# Implementing add

- How do we add to the end of a list?

```
public void add(int value) {    // just put the element
    list[size] = value;          // in the last slot,
    size++;                      // and increase the size
}
```

| index | 0 | 1 | 2 | 3 | 4 | 5  | 6 | 7 | 8 | 9 |
|-------|---|---|---|---|---|----|---|---|---|---|
| value | 3 | 8 | 9 | 7 | 5 | 12 | 0 | 0 | 0 | 0 |
| size  | 6 |   |   |   |   |    |   |   |   |   |

- `list.add(42);`

| index | 0 | 1 | 2 | 3 | 4 | 5  | 6  | 7 | 8 | 9 |
|-------|---|---|---|---|---|----|----|---|---|---|
| value | 3 | 8 | 9 | 7 | 5 | 12 | 42 | 0 | 0 | 0 |
| size  | 7 |   |   |   |   |    |    |   |   |   |

# Implementing add #2

- How do we add to the middle or end of the list?
  - must *shift* elements to make room for the value (*see book 7.3*)

| index | 0 | 1 | 2 | 3 | 4 | 5  | 6 | 7 | 8 | 9 |
|-------|---|---|---|---|---|----|---|---|---|---|
| value | 3 | 8 | 9 | 7 | 5 | 12 | 0 | 0 | 0 | 0 |
| size  | 6 |   |   |   |   |    |   |   |   |   |

– `list.add(3, 42); // insert 42 at index 3`

| index | 0 | 1 | 2 | 3  | 4 | 5 | 6  | 7 | 8 | 9 |
|-------|---|---|---|----|---|---|----|---|---|---|
| value | 3 | 8 | 9 | 42 | 7 | 5 | 12 | 0 | 0 | 0 |
| size  | 7 |   |   |    |   |   |    |   |   |   |

– Note: The order in which you traverse the array matters!

# add #2 code

```
public void add(int index, int value) {  
    for (int i = size; i > index; i--) {  
        list[i] = list[i - 1];  
    }  
    list[index] = value;  
}
```

| <i>index</i> | 0 | 1 | 2 | 3 | 4 | 5  | 6 | 7 | 8 | 9 |
|--------------|---|---|---|---|---|----|---|---|---|---|
| <i>value</i> | 3 | 8 | 9 | 7 | 5 | 12 | 0 | 0 | 0 | 0 |
| <i>size</i>  | 6 |   |   |   |   |    |   |   |   |   |

- `list.add(3, 42);`

| <i>index</i> | 0 | 1 | 2 | 3  | 4 | 5 | 6  | 7 | 8 | 9 |
|--------------|---|---|---|----|---|---|----|---|---|---|
| <i>value</i> | 3 | 8 | 9 | 42 | 7 | 5 | 12 | 0 | 0 | 0 |
| <i>size</i>  | 7 |   |   |    |   |   |    |   |   |   |

# Other methods

- Let's implement the following methods in our list:
  - `get(index)`  
Returns the element value at a given index.
  - `set(index, value)`  
Sets the list to store the given value at the given index.
  - `size()`  
Returns the number of elements in the list.
  - `isEmpty()`  
Returns `true` if the list contains no elements; `false`.  
(Why write this if we already have the `size` method?)

# Implementing remove

- How can we remove an element from the list?

| <i>index</i> | 0 | 1 | 2 | 3 | 4 | 5  | 6 | 7 | 8 | 9 |
|--------------|---|---|---|---|---|----|---|---|---|---|
| <i>value</i> | 3 | 8 | 9 | 7 | 5 | 12 | 0 | 0 | 0 | 0 |
| <i>size</i>  | 6 |   |   |   |   |    |   |   |   |   |

- `list.remove(2); // delete 9 from index 2`

| <i>index</i> | 0 | 1 | 2 | 3 | 4  | 5 | 6 | 7 | 8 | 9 |
|--------------|---|---|---|---|----|---|---|---|---|---|
| <i>value</i> | 3 | 8 | 7 | 5 | 12 | 0 | 0 | 0 | 0 | 0 |
| <i>size</i>  | 5 |   |   |   |    |   |   |   |   |   |

# Implementing remove, cont.

- Again, we need to shift elements in the array
  - this time, it's a left-shift
  - in what order should we process the elements?
  - what indexes should we process?

| index | 0 | 1 | 2 | 3 | 4 | 5  | 6 | 7 | 8 | 9 |
|-------|---|---|---|---|---|----|---|---|---|---|
| value | 3 | 8 | 9 | 7 | 5 | 12 | 0 | 0 | 0 | 0 |
| size  | 6 |   |   |   |   |    |   |   |   |   |

– `list.remove(2); // delete 9 from index 2`

| index | 0 | 1 | 2 | 3 | 4  | 5 | 6 | 7 | 8 | 9 |
|-------|---|---|---|---|----|---|---|---|---|---|
| value | 3 | 8 | 7 | 5 | 12 | 0 | 0 | 0 | 0 | 0 |
| size  | 5 |   |   |   |    |   |   |   |   |   |

# Implementing remove code

```
public void remove(int index) {  
    for (int i = index; i < size; i++) {  
        list[i] = list[i + 1];  
    }  
    size--;  
    list[size] = 0;          // optional (why?)  
}
```

| index | 0 | 1 | 2 | 3 | 4 | 5  | 6 | 7 | 8 | 9 |
|-------|---|---|---|---|---|----|---|---|---|---|
| value | 3 | 8 | 9 | 7 | 5 | 12 | 0 | 0 | 0 | 0 |
| size  | 6 |   |   |   |   |    |   |   |   |   |

- `list.remove(2); // delete 9 from index 2`

| index | 0 | 1 | 2 | 3 | 4  | 5 | 6 | 7 | 8 | 9 |
|-------|---|---|---|---|----|---|---|---|---|---|
| value | 3 | 8 | 7 | 5 | 12 | 0 | 0 | 0 | 0 | 0 |
| size  | 5 |   |   |   |    |   |   |   |   |   |

# Printing an ArrayIntList

- Let's add a method that allows clients to print a list's elements.
  - You may be tempted to write a `print` method:

```
// client code  
ArrayIntList list = new ArrayIntList();  
...  
list.print();
```

- Why is this a bad idea? What would be better?

# The `toString` method

- Tells Java how to convert an object into a `String`

```
ArrayIntList list = new ArrayIntList();
System.out.println("list is " + list);
// ("list is " + list.toString());
```

- Syntax:

```
public String toString() {
    code that returns a suitable String;
}
```

- Every class has a `toString`, even if it isn't in your code.
  - The default is the class's name and a hex (base-16) number:

```
ArrayIntList@9e8c34
```

# toString solution

```
// Returns a String representation of the list.  
public String toString() {  
    if (size == 0) {  
        return "[]";  
    } else {  
        String result = "[" + elementData[0];  
        for (int i = 1; i < size; i++) {  
            result += ", " + elementData[i];  
        }  
        result += "]";  
        return result;  
    }  
}
```

# Searching methods

- Implement the following methods:
  - `indexOf` - returns the first index an element is found, or `-1` if not
  - `contains` - returns true if the list contains the given int value
- Why do we need `isEmpty` and `contains` when we already have `indexOf` and `size`?
  - Adds convenience to the client of our class:

// less elegant

```
if (myList.size() == 0) {  
    if (myList.indexOf(42) >= 0) {
```

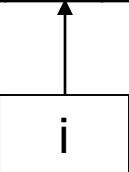

// more elegant

```
if (myList.isEmpty()) {  
    if (myList.contains(42)) {
```

# Sequential search

- **sequential search:** Locates a target value in an array / list by examining each element from start to finish. Used in `indexOf`.
  - How many elements will it need to examine?
  - Example: Searching the array below for the value **42**:

| index | 0  | 1 | 2 | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10 | 11 | 12 | 13 | 14 | 15 | 16  |
|-------|----|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|-----|
| value | -4 | 2 | 7 | 10 | 15 | 20 | 22 | 25 | 30 | 36 | 42 | 50 | 56 | 68 | 85 | 92 | 103 |
| i     |    |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |     |

- Notice that the array is sorted. Could we take advantage of this?

# Binary search (13.1)

- **binary search:** Locates a target value in a *sorted* array / list by successively eliminating half of the array from consideration.
  - How many elements will it need to examine?
  - Example: Searching the array below for the value **42**:

| index | 0  | 1 | 2 | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10 | 11 | 12 | 13 | 14 | 15 | 16  |
|-------|----|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|-----|
| value | -4 | 2 | 7 | 10 | 15 | 20 | 22 | 25 | 30 | 36 | 42 | 50 | 56 | 68 | 85 | 92 | 103 |

The diagram illustrates the state of a binary search algorithm on the provided array. Three variables are tracked: **min** (minimum value), **mid** (middle index), and **max** (maximum value). Arrows point from each variable to its corresponding element in the array. **min** points to index 0 (-4). **mid** points to index 10 (42). **max** points to index 16 (103).

# Arrays.binarySearch

```
// searches an entire sorted array for a given value  
// returns its index if found; a negative number if not found  
// Precondition: array is sorted  
Arrays.binarySearch(array, value)
```

```
// searches given portion of a sorted array for a given value  
// examines minIndex (inclusive) through maxIndex (exclusive)  
// returns its index if found; a negative number if not found  
// Precondition: array is sorted  
Arrays.binarySearch(array, minIndex, maxIndex, value)
```

- The binarySearch method in the Arrays class searches an array very efficiently if the array is sorted.
  - You can search the entire array, or just a range of indexes (useful for "unfilled" arrays such as the one in ArrayIntList)

# Using binarySearch

```
// index    0  1  2  3  4  5  6  7  8  9  10  11  12  13  14  15
int[] a = {-4, 2, 7, 9, 15, 19, 25, 28, 30, 36, 42, 50, 56, 68, 85, 92};

int index  = Arrays.binarySearch(a, 0, 16, 42);      // index1 is 10
int index2 = Arrays.binarySearch(a, 0, 16, 21);      // index2 is -7
```

- `binarySearch` returns the index where the value is found
- if the value is *not* found, `binarySearch` returns:
  - $(\text{insertionPoint} + 1)$
- where `insertionPoint` is the index where the element *would* have been, if it had been in the array in sorted order.
- To insert the value into the array, negate `insertionPoint + 1`

```
int indexToInsert21 = -(index2 + 1); // 6
```
