Programming Assignment #4: Evil Hangman (40 points)

Due Thursday, April 27, 2017, 11:30 PM

thanks to Keith Schwarz from Stanford for this project idea!

This program focuses on programming with Java Collections classes. Turn in a file named `HangmanManager.java` from the Homework section of the course web site. You will need support files `HangmanMain.java`, `dictionary.txt`, and other input files from the Homework section of the course web site; place them in the same folder as your project.

The Game of Hangman:

In a normal game of hangman, the computer picks a word that the user is supposed to guess. The user then guesses individual letters until the word is fully discovered. If you aren't familiar with the general rules of the game of hangman, review its Wikipedia page: [http://en.wikipedia.org/wiki/Hangman_\(game\)](http://en.wikipedia.org/wiki/Hangman_(game)).

```
Welcome to the cse143 hangman game.

What length word do you want to use? 4
How many wrong answers allowed? 7

guesses : 7
guessed : []
current : - - - -
Your guess? e
Sorry, there are no e's

guesses : 6
guessed : [e]
current : - - - -
Your guess? o
Yes, there are 2 o's

guesses : 6
guessed : [e, o]
current : - o o -
Your guess? c
Sorry, there are no c's

guesses : 5
guessed : [c, e, o]
current : - o o -
Your guess? g
Yes, there is one g

guesses : 5
guessed : [c, e, g, o]
current : g o o -
Your guess? d
Yes, there is one d

answer = good
You beat me
```

In our game of hangman, the computer delays picking a word until it is forced to. As a result, the computer is always considering a set of words that could be the answer. In order to fool the user into thinking it is playing fairly, the computer only considers words with the same letter pattern.

For example, suppose that the computer knows the words in the following dictionary (`dictionary2.txt`):

```
ally beta cool deal else flew good hope ibex
```

In a normal game of hangman, the computer would start the game by choosing a word to guess. In our game, the computer doesn't yet commit to an answer but instead narrows down its set of possible answers as the user makes guesses.

In the log at left, the user's first guess is 'e'. The computer has to reveal where the letter 'e' appears but since it hasn't chosen an answer, it has several options. In particular, note that the dictionary's words fall into 5 families:

- ---- is the pattern for [ally, cool, good]
- -e-- is the pattern for [beta, deal]
- --e- is the pattern for [flew, ibex]
- ---e is the pattern for [hope]
- e--e is the pattern for [else]

The computer could choose to reveal any of these 5 patterns. It could use several different strategies for picking the family to display. For this project, your program will always choose the largest of the remaining word families. This will leave the computer's options open and increase its chances of winning.

For the example described above, the computer would pick ----. This reduces the possible answers it can consider to:

```
ally cool good
```

Since the computer didn't reveal any letters, it counts this as a wrong guess and decreases the number of guesses left to 6. Next, the user guesses the letter 'o'. The computer has two word families to consider:

- -oo- is the pattern for [cool, good]
- ---- is the pattern for [ally]

It picks the biggest family and reveals the letter 'o' in two places. This was a correct guess so the user still has 6 guesses left. The computer now has only two possible answers to choose from:

```
cool good
```

When the user picks 'c', the computer removes 'cool' from its consideration and is now locked into using 'good' as the answer. With a large dictionary, it will take much longer for the computer to have to pick an answer!

Implementation Details:

You are given a client program `HangmanMain.java` that does the file processing and user interaction. `HangmanMain` reads a dictionary text file as input and passes its entire contents to you as a list of strings. You are to write a class called `HangmanManager` that will manage the state of the game.

Your class should have the following public methods:

```
public HangmanManager(List<String> dictionary, int length, int max)
```

Your constructor is passed a dictionary of words, a target word length and the maximum number of wrong guesses the player is allowed to make. It should use these values to initialize the state of the game. The set of words should initially be all words from the dictionary that are of the given length.

You should throw an `IllegalArgumentException` if `length` is less than 1 or if `max` is less than 0.

```
public Set<String> words()
```

The client calls this method to get access to the current set of words being considered by the `HangmanManager`.

```
public int guessesLeft()
```

The client calls this method to find out how many guesses the player has left.

```
public SortedSet<Character> guesses()
```

The client calls this method to find out the current set of letters that have been guessed by the user.

```
public String pattern()
```

This method should return the current pattern to be displayed for the hangman game taking into account guesses that have been made. Letters that have not yet been guessed should be displayed as a dash and there should be spaces separating the letters. There should be no leading or trailing spaces.

This method should throw an `IllegalStateException` if the set of words is empty.

```
public int record(char guess)
```

This is the method that does most of the work by recording the next guess made by the user. Using this guess, it should decide what set of words to use going forward. It should return the number of occurrences of the guessed letter in the new pattern and it should appropriately update the number of guesses left.

This method should throw an `IllegalStateException` if the number of guesses left is not at least 1 or if the list of words is empty. It should throw an `IllegalArgumentException` if the list of words is nonempty and the character being guessed was guessed previously.

Your program should exactly reproduce the format and general behavior demonstrated on the previous page.

You may assume that the list of words passed to your constructor will be a nonempty list of nonempty strings composed entirely of lowercase letters. You may also assume that all guesses passed to your `record` method are lowercase letters.

Notice that the `guesses` method returns a `SortedSet` rather than a `Set`. `SortedSet` is a variation of the `Set` interface that requires that the values in the set are to appear in increasing order. We want this property for the set of guesses so that we can show the user the guesses in alphabetical order. The `TreeSet` class implements this interface, just as `TreeSet` implements the `Set` interface. Also notice that the set returned is a set of `Character` values. Recall that type parameters must be object types and that `Character` is the wrapper class for `char` values. You can generally manipulate the set as if it were a set of simple `char` values (e.g., calling `add` or `contains` with a simple `char` value).

The `pattern` and `record` methods throw an exception when the list of words is empty. The only way this can happen is if the client requests a word length for which there are no matches in the dictionary. For example, the dictionary does not have any words of length 25.

For each call on `record`, you will find all of the possible word families and pick the one that has the most elements. Use a `Map` to associate family patterns with the set of words that have each pattern. If there is a tie (two of the word families are of equal size), you should pick the one that occurs earlier in the `Map` (i.e., the one whose key comes up first when you iterate over the key set). The set of words representing the biggest family then becomes the dictionary for the next round.

Use the `TreeSet` and `TreeMap` implementations for all of your sets and maps.

Development Strategy and Hints:

The hardest method is **record**, so write it last. The friends program from lecture provides several useful ideas.

Create a simple test client to verify behavior as you add it. For example, write code to produce a Hangman-style clue (with dashes for letters that have not been guessed) and verify that it works in your simple client. Another good task to complete and test in isolation is building the map that associates word family patterns to words in that family.

HangmanMain has two constants that you will want to change. The first represents the name of the dictionary file. By default, it reads from `dictionary.txt` which contains over 127,000 words from the official English Scrabble dictionary. When getting started, change it to `dictionary2.txt` which contains the 9 words used in the example on the first page. `DEBUG` is set to `false` by default. Set it to `true` to see the words the computer is still considering as you play.

Here is a diagram showing the decisions made by the computer in the scenario described on the first page:

Style Guidelines and Grading:

You should introduce private methods to avoid redundancy and to break up large methods into smaller methods. In particular, **you should not have any methods that have more than 20 lines of code in their body** (not counting blank lines and lines that have just comments or curly braces). If you have a method that requires more than 20 lines of code, then you should break it up into smaller methods.

You should always use generic structures. If you make a mistake in specifying type parameters, the Java compiler may warn you that you have “unchecked or unsafe operations” in your program. If you use jGRASP, you may want to change your settings to see which line the warning refers to. Go to `Settings/Compiler Settings/Workspace/Flags/Args` and then uncheck the box next to “Compile” and type in: `-Xlint:unchecked`

You should follow general good style guidelines such as: making fields `private` and avoiding unnecessary fields; declaring collection variables using interface types; appropriately using control structures like loops and `if/else`; properly using indentation, good variable names and types; and not having any lines of code longer than 100 characters.

Comment your code descriptively in your own words at the top of your class, each method, and on complex sections of your code. Comments should explain each method's behavior, parameters, return, pre/post-conditions, and exceptions. For reference, our solution is around 147 lines long including comments and blank lines (73 “substantive” lines).
