# Exercise: Dice rolls

- Write a method `diceRoll` that accepts an integer parameter representing a number of 6-sided dice to roll, and output all possible arrangements of values that could appear on the dice.

```
diceRoll(2);
```

[1, 1]	[3, 1]	[5, 1]
[1, 2]	[3, 2]	[5, 2]

# Examining the problem

- We want to generate all possible sequences of values.

```
for (each possible first die value):
```

```
    for (each possible second die value):
```

```
        for (each possible third die value):
```

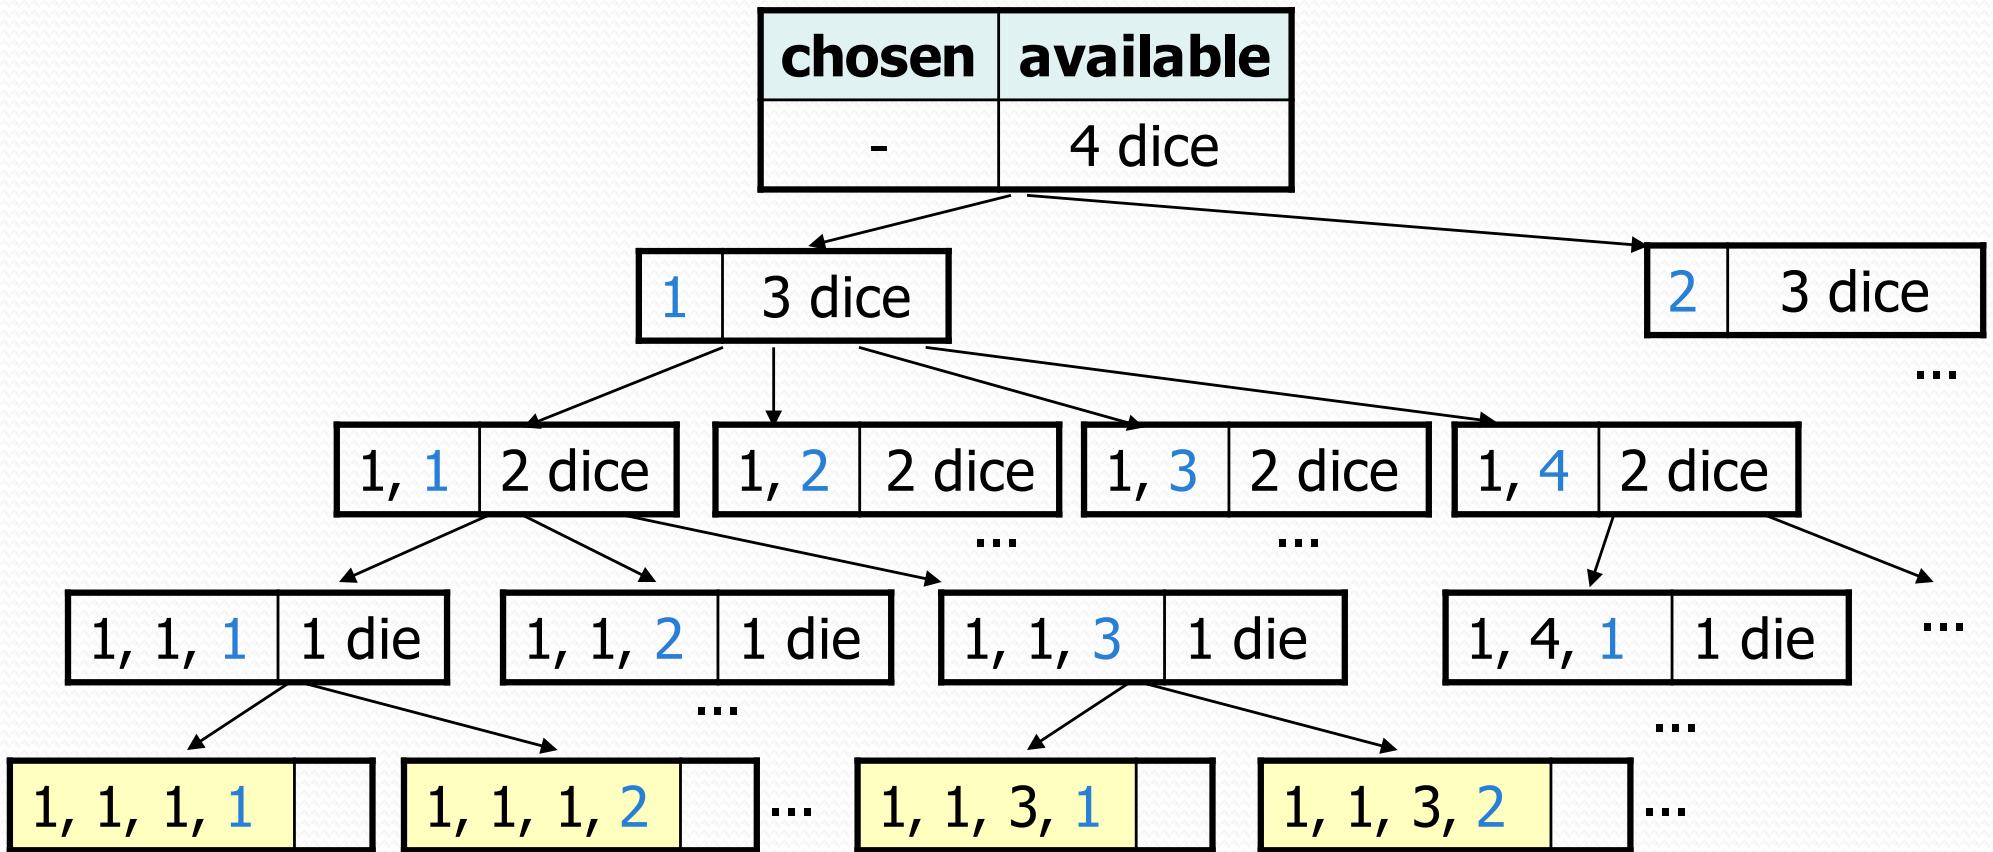

```
        ...
```

```
    print!
```

- This is called a **depth-first search**
- How can we completely explore such a large search space?

# A decision tree

# Solving recursively

- Pick a value for the first die
- Recursively find values for the remaining dice
- Repeat with other values for the first die
- What is the base case?

# Private helpers

- Often the method doesn't accept the parameters you want.
  - So write a **private helper** that accepts more parameters.
  - Extra params can represent current state, choices made, etc.

```
public int methodName(params) :  
    ...  
    return helper(params, moreParams) ;
```

```
private int helper(params, moreParams) :  
    ...  
(use moreParams to help solve the problem)
```

# Exercise solution

```
// Prints all possible outcomes of rolling the given
// number of six-sided dice in [#, #, #] format.
public static void diceRolls(int dice) {
    List<Integer> chosen = new ArrayList<Integer>();
    diceRolls(dice, chosen);
}

// private recursive helper to implement diceRolls logic
private static void diceRolls(int dice,
                           List<Integer> chosen) {
    if (dice == 0) {
        System.out.println(chosen); // base case
    } else {
        for (int i = 1; i <= 6; i++) {
            chosen.add(i); // choose
            diceRolls(dice - 1, chosen); // explore
            chosen.remove(chosen.size() - 1); // un-choose
        }
    }
}
```

# Exercise: Dice roll sum

- Write a method `diceSum` similar to `diceRoll`, but it also accepts a desired sum and prints only arrangements that add up to exactly that sum.

```
diceSum(2, 7);
```

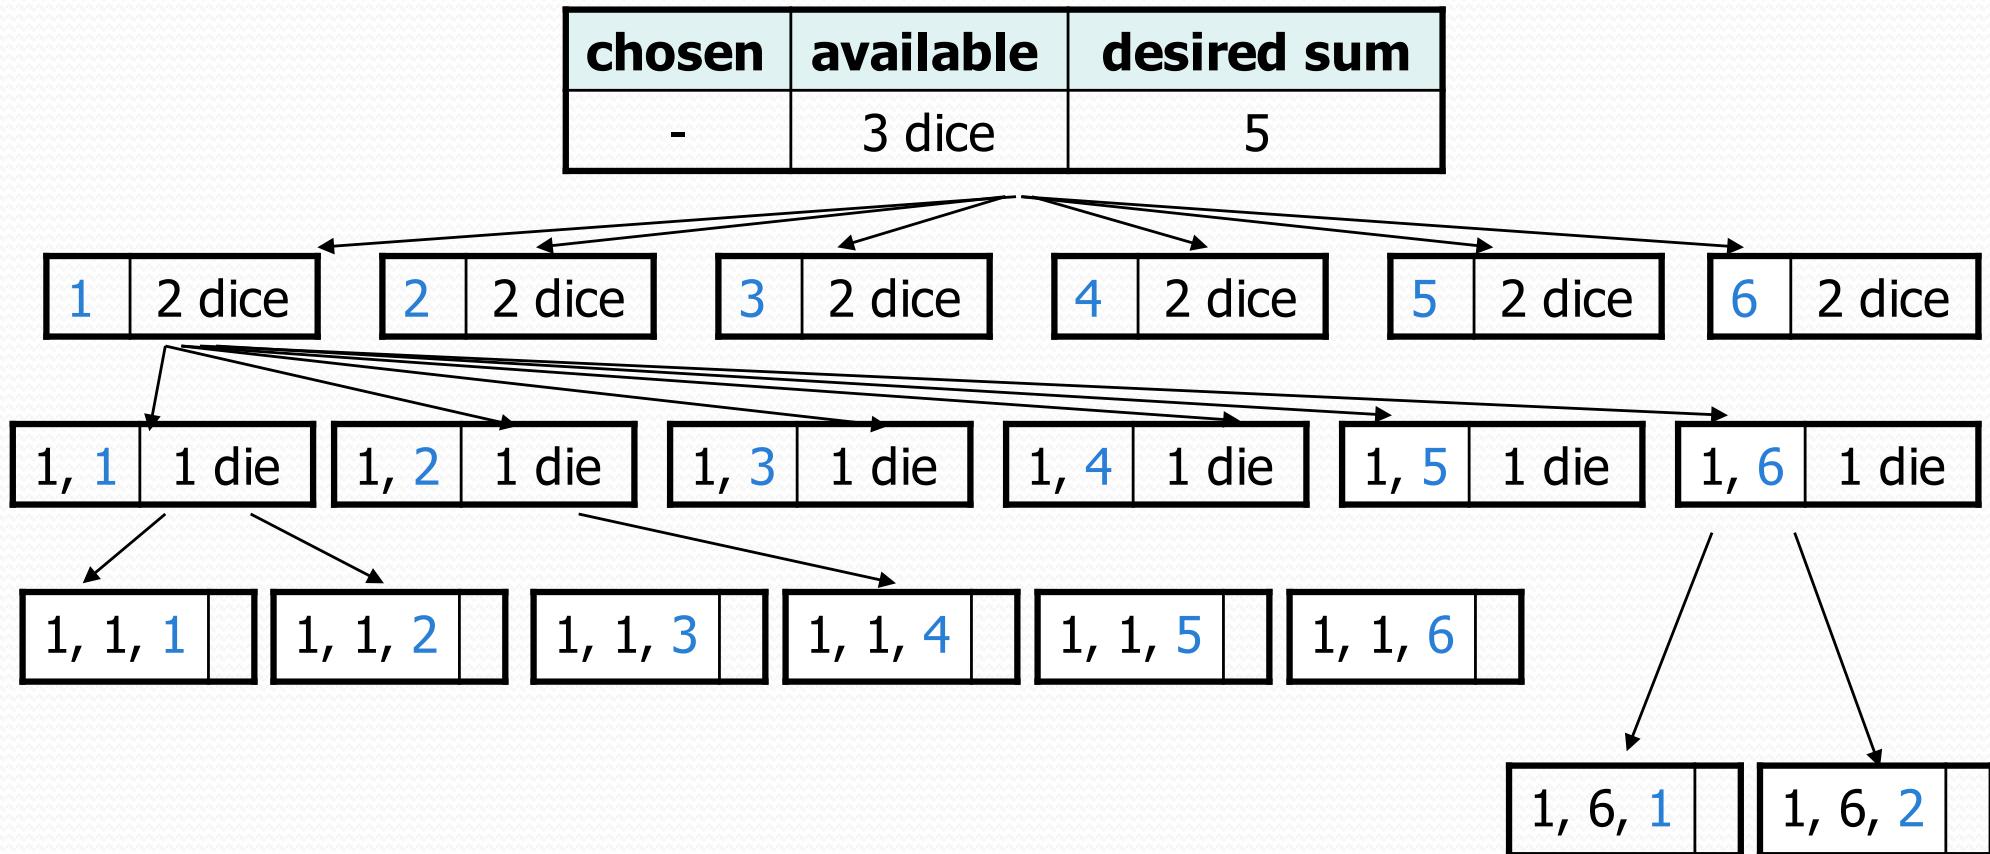

```
[1, 6]  
[2, 5]  
[3, 4]  
[4, 3]  
[5, 2]  
[6, 1]
```

```
diceSum(3, 7);
```

```
[1, 1, 5]  
[1, 2, 4]  
[1, 3, 3]  
[1, 4, 2]  
[1, 5, 1]  
[2, 1, 4]  
[2, 2, 3]  
[2, 3, 2]  
[2, 4, 1]  
[3, 1, 3]  
[3, 2, 2]  
[3, 3, 1]  
[4, 1, 2]  
[4, 2, 1]  
[5, 1, 1]
```

# Consider all paths?

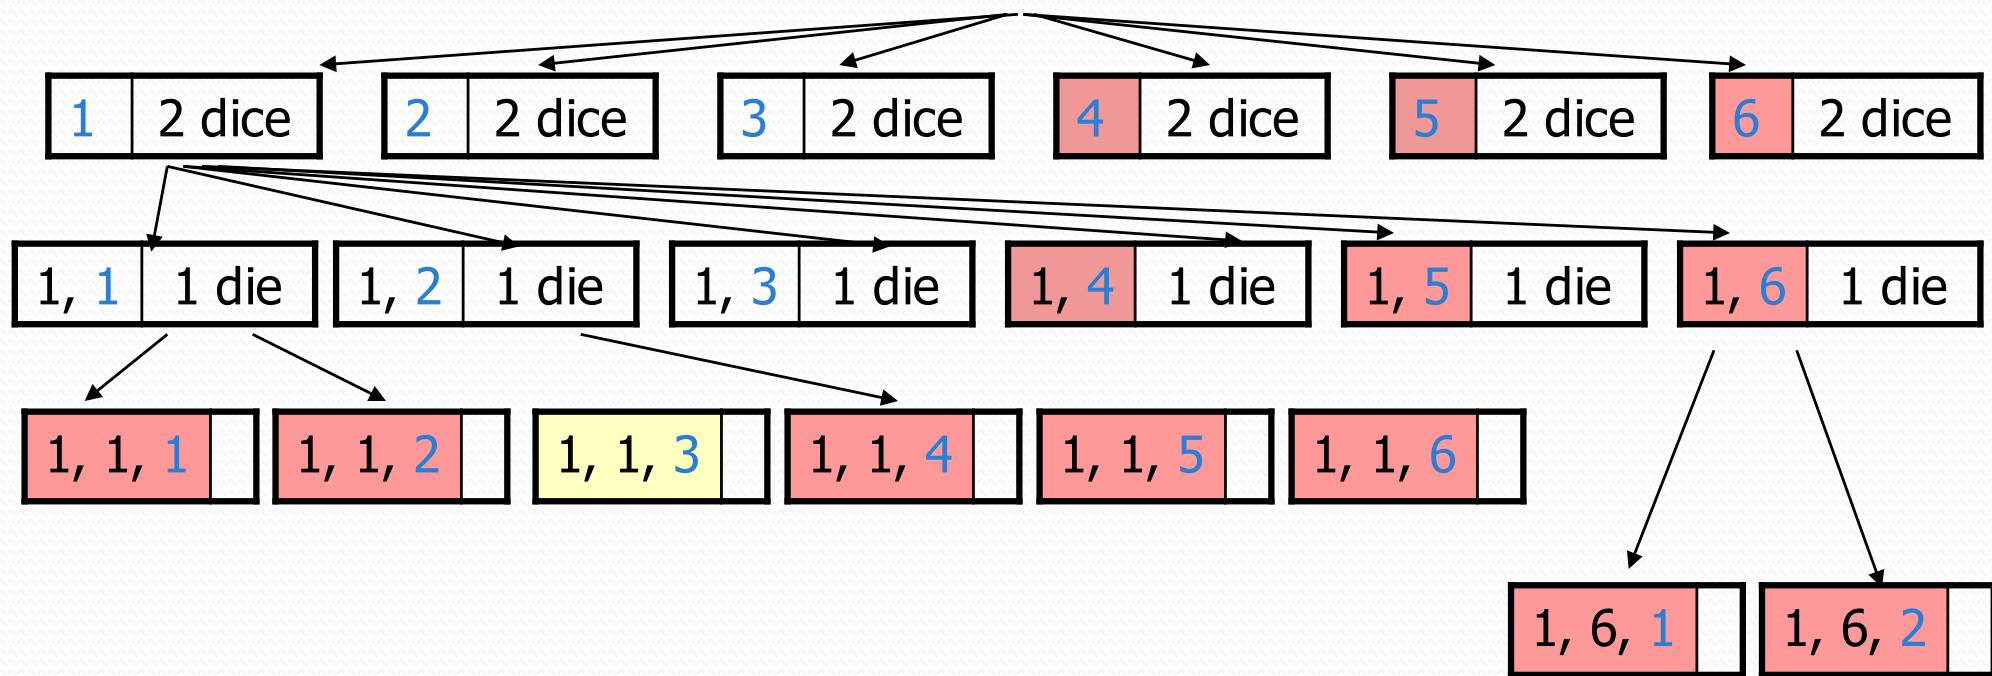

# Optimizations

- We need not visit every branch of the decision tree.
  - Some branches are clearly not going to lead to success.
  - We can preemptively stop, or **prune**, these branches.
- Inefficiencies in our dice sum algorithm:
  - Sometimes the current sum is already too high.
    - (Even rolling 1 for all remaining dice would exceed the sum.)
  - Sometimes the current sum is already too low.
    - (Even rolling 6 for all remaining dice would not reach the sum.)
  - When finished, the code must compute the sum every time.
    - ( $1+1+1 = \dots, 1+1+2 = \dots, 1+1+3 = \dots, 1+1+4 = \dots, \dots$ )

# New decision tree

<b>chosen</b>	<b>available</b>	<b>desired sum</b>
-	3 dice	5

10

# Backtracking

- **backtracking**: Finding solution(s) by trying partial solutions and then abandoning them if they are not suitable.
  - a "brute force" algorithmic technique (tries all paths)
  - often implemented recursively

Applications:

- producing all permutations of a set of values
- parsing languages
- games: anagrams, crosswords, word jumbles, 8 queens
- combinatorics and logic programming

# Backtracking algorithms

*A general pseudo-code algorithm for backtracking problems:*

Explore(**choices**):

- if there are no more **choices** to make: stop.
- else:
  - Make a single choice **C**.
  - Explore the remaining **choices**.
  - Un-make choice **C**, if necessary. (backtrack!)

# Exercise solution, improved

```
public static void diceSum(int dice, int desiredSum) {  
    List<Integer> chosen = new ArrayList<Integer>();  
    diceSum2(dice, desiredSum, chosen, 0);  
}  
  
private static void diceSum(int dice, int desiredSum,  
                           List<Integer> chosen, int sumSoFar) {  
    if (dice == 0) {  
        if (sumSoFar == desiredSum) {  
            System.out.println(chosen);  
        }  
    } else if (sumSoFar < desiredSum &&  
               sumSoFar + 6 * dice >= desiredSum) {  
        for (int i = 1; i <= 6; i++) {  
            chosen.add(i);  
            diceSum(dice - 1, desiredSum, chosen, sumSoFar +  
                    i);  
            chosen.remove(chosen.size() - 1);  
        }  
    }  
}
```

# Backtracking strategies

- When solving a backtracking problem, ask these questions:
  - What are the "choices" in this problem?
    - What is the "base case"? (How do I know when I'm out of choices?)
  - How do I "make" a choice?
    - Do I need to create additional variables to remember my choices?
    - Do I need to modify the values of existing variables?
  - How do I explore the rest of the choices?
    - Do I need to remove the made choice from the list of choices?
  - Once I'm done exploring, what should I do?
  - How do I "un-make" a choice?

# Exercise: Combinations

- Write a method `combinations` that accepts a string  $s$  and an integer  $k$  as parameters and outputs all possible  $k$ -letter words that can be formed from unique letters in that string. The arrangements may be output in any order.
  - Example:  
`combinations ("GOOGLE", 3)`  
outputs the sequence of  
lines at right.
  - To simplify the problem, you may assume  
that the string  $s$  contains at least  $k$   
unique characters.

GLO	OGL
GOE	OLE
GOL	OLG

# Initial attempt

```
public static void combinations(String s, int length) {  
    combinations(s, "", length);  
}  
  
private static void combinations(String s, String chosen, int length) {  
    if (length == 0) {  
        System.out.println(chosen);      // base case: no choices left  
    } else {  
        for (int i = 0; i < s.length(); i++) {  
            String ch = s.substring(i, i + 1);  
            if (!chosen.contains(ch)) {  
                String rest = s.substring(0, i) + s.substring(i + 1);  
                combinations(rest, chosen + ch, length - 1);  
            }  
        }  
    }  
}
```

- Problem: Prints same string multiple times.

# Exercise solution

```
public static void combinations(String s, int length) {  
    Set<String> all = new TreeSet<String>();  
    combinations(s, "", all, length);  
    for (String comb : all) {  
        System.out.println(comb);  
    }  
}  
  
private static void combinations(String s, String chosen,  
                                Set<String> all, int length) {  
    if (length == 0) {  
        all.add(chosen); // base case: no choices left  
    } else {  
        for (int i = 0; i < s.length(); i++) {  
            String ch = s.substring(i, i + 1);  
            if (!chosen.contains(ch)) {  
                String rest = s.substring(0, i) + s.substring(i + 1);  
                combinations(rest, chosen + ch, all, length - 1);  
            }  
        }  
    }  
}
```
