Building Java Programs

Chapter 12
recursive programming

reading: 12.2 - 12.4
public static int method(int n) {
    if (n <= 1) {
        return 1;
    } else {
        return method(n - 2) + method(n - 1);
    }
}

What is the value returned by method(5)?
Recursion and cases

• Every recursive algorithm involves at least 2 cases:
  • **base case**: simple problem that can be solved directly.
  • **recursive case**: more complex occurrence of the problem that cannot be directly answered, but can instead be described in terms of smaller occurrences of the same problem.

• Some recursive algorithms have more than one base or recursive case, but all have at least one of each.
• A crucial part of recursive programming is identifying these cases.
Tracing our algorithm

- **call stack**: The method invocations currently running

```java
reverseLines(new Scanner("poem.txt"));
```

```
public static void reverseLines(Scanner input) {
    if (input.hasNextLine()) {
        String line = input.nextLine(); // "I have eaten"
    }
}
```

```
public static void reverseLines(Scanner input) {
    if (input.hasNextLine()) {
        String line = input.nextLine(); // "the plums"
    }
}
```

```
public static void reverseLines(Scanner input) {
    if (input.hasNextLine()) {
        String line = input.nextLine(); // "that were in"
    }
}
```

```
public static void reverseLines(Scanner input) {
    if (input.hasNextLine()) {
        String line = input.nextLine(); // "the icebox"
    }
}
```

```
public static void reverseLines(Scanner input) {
    if (input.hasNextLine()) {
        // false
    }
    ...
}
```

I have eaten
the plums
that were in
the icebox
the icebox
that were in
the plums
I have eaten
Exercise

• Write a recursive method $\text{pow}$ accepts an integer base and exponent and returns the base raised to that exponent.
  • Example: $\text{pow}(3, 4)$ returns 81

• Solve the problem recursively and without using loops.
An optimization

- Notice the following mathematical property:
  \[3^{12} = 531441 = 9^6 = (3^2)^6\]
  \[531441 = (9^2)^3 = ((3^2)^2)^3\]

- When does this "trick" work?
- How can we incorporate this optimization into our `pow` method?
- What is the benefit of this trick if the method already works?
Write a recursive method `printBinary` that accepts an integer and prints that number's representation in binary (base 2).

Example: `printBinary(7)` prints 111
Example: `printBinary(12)` prints 1100
Example: `printBinary(42)` prints 101010

Write the method recursively and without using any loops.
Repeat Digits

- How did we break the number apart?

```java
public static int repeatDigits(int n) {
    if (n < 10) {
        return (10 * n) + n;
    } else {
        int a = repeatDigits(n / 10);
        int b = repeatDigits(n % 10);
        return (100 * a) + b;
    }
}
```
Case analysis

- Recursion is about solving a small piece of a large problem.
  - What is 69743 in binary?
    - Do we know *anything* about its representation in binary?
  - Case analysis:
    - What is/are easy numbers to print in binary?
    - Can we express a larger number in terms of a smaller number(s)?
printBinary solution

// Prints the given integer's binary representation.
// Precondition: n >= 0
public static void printBinary(int n) {
    if (n < 2) {
        // base case; same as base 10
        System.out.println(n);
    } else {
        // recursive case; break number apart
        printBinary(n / 2);
        printBinary(n % 2);
    }
}

• Can we eliminate the precondition and deal with negatives?
Exercise

• Write a recursive method `isPalindrome` accepts a `String` and returns `true` if it reads the same forwards as backwards.

```java
• isPalindrome("madam") → true
• isPalindrome("racecar") → true
• isPalindrome("step on no pets") → true
• isPalindrome("able was I ere I saw elba") → true
• isPalindrome("Java") → false
• isPalindrome("rotater") → false
• isPalindrome("byebye") → false
• isPalindrome("notion") → false
```
// Returns true if the given string reads the same // forwards as backwards. // Trivially true for empty or 1-letter strings.
public static boolean isPalindrome(String s) {
    if (s.length() < 2) {
        return true; // base case
    } else {
        char first = s.charAt(0);
        char last = s.charAt(s.length() - 1);
        if (first != last) {
            return false;
        } // recursive case
        String middle = s.substring(1, s.length() - 1);
        return isPalindrome(middle);
    }
}
// Returns true if the given string reads the same
// forwards as backwards.
// Trivially true for empty or 1-letter strings.
public static boolean isPalindrome(String s) {
    if (s.length() < 2) {
        return true; // base case
    } else {
        return s.charAt(0) == s.charAt(s.length() - 1)
            && isPalindrome(s.substring(1, s.length() - 1));
    }
}
Exercise

- Write a method `print` accepts a `File` parameter and prints information about that file.
  - If the `File` object represents a normal file, just print its name.
  - If the `File` object represents a directory, print its name and information about every file/directory inside it, indented.

```
cse143
  handouts
    syllabus.doc
    lecture_schedule.xls
  homework
    1-tiles
      TileMain.java
      TileManager.java
    index.html
    style.css
```

- **recursive data**: A directory can contain other directories.
Recursive Data

- A file is one of
  - A simple file
  - A directory containing files
- Directories can be nested to an arbitrary depth
File objects

- A File object (from the java.io package) represents a file or directory on the disk.

<table>
<thead>
<tr>
<th>Constructor/method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File(String)</td>
<td>creates File object representing file with given name</td>
</tr>
<tr>
<td>canRead()</td>
<td>returns whether file is able to be read</td>
</tr>
<tr>
<td>delete()</td>
<td>removes file from disk</td>
</tr>
<tr>
<td>exists()</td>
<td>whether this file exists on disk</td>
</tr>
<tr>
<td>getName()</td>
<td>returns file's name</td>
</tr>
<tr>
<td>isDirectory()</td>
<td>returns whether this object represents a directory</td>
</tr>
<tr>
<td>length()</td>
<td>returns number of bytes in file</td>
</tr>
<tr>
<td>listFiles()</td>
<td>returns a File[] representing files in this directory</td>
</tr>
<tr>
<td>renameTo(File)</td>
<td>changes name of file</td>
</tr>
</tbody>
</table>
Public/private pairs

- We cannot vary the indentation without an extra parameter:

  ```java
  public static void crawl(File f, String indent) {
  ```

- Often the parameters we need for our recursion do not match those the client will want to pass.

  In these cases, we instead write a pair of methods:
  1) a **public**, non-recursive one with parameters the client wants
  2) a **private**, recursive one with the parameters we really need
Exercise solution 2

// Prints information about this file, 
// and (if it is a directory) any files inside it. 
public static void crawl(File f) {
    crawl(f, ""); // call private recursive helper 
}

// Recursive helper to implement crawl/indent 
// behavior. 
private static void crawl(File f, String indent) {
    System.out.println(indent + f.getName());
    if (f.isDirectory()) {
        // recursive case; print contained files/dirs 
        File[] subFiles = f.listFiles();
        for (int i = 0; i < subFiles.length; i++) {
            crawl(subFiles[i], indent + "    ");
        }
    }
}
Recursion Challenges

- Forgetting a base case
  - Infinite recursion resulting in StackOverflowError

- Working away from the base case
  - The recursive case must make progress towards the base case
  - Infinite recursion resulting in StackOverflowError

- Running out of memory
  - Even when making progress to the base case, some inputs may require too many recursive calls: StackOverflowError

- Recomputing the same subproblem over and over again
  - Refining the algorithm could save significant time
