Chapter 11
Sets and Maps

reading: 11.2 - 11.3

Sets (11.2)

- **set**: A collection of unique values (no duplicates allowed) that can perform the following operations efficiently:
 - add, remove, search (contains)
- We don't think of a set as having indexes; we just add things to the set in general and don't worry about order

Set methods

In Java, Set is an interface that allows you to call the following methods

<code>add (value)</code>	adds the given value to the set. If the value is already in the set, nothing happens
<code>contains (value)</code>	returns <code>true</code> if the given value is found in this set
<code>remove (value)</code>	removes the given value from the set
<code>clear ()</code>	removes all elements of the set
<code>size ()</code>	returns the number of elements in list
<code>isEmpty ()</code>	returns <code>true</code> if the set's size is 0
<code>toString ()</code>	returns a string such as "[3, 42, -7, 15]"

Set implementation

- in Java, sets are represented by `Set` interface in `java.util`
- `Set` is implemented by `HashSet` and `TreeSet` classes
 - `HashSet`: implemented using a "hash table";
extremely fast for all operations
elements are stored in unpredictable order
 - `TreeSet`: implemented using a "binary search tree";
very fast for all operations
elements are stored in sorted order

```
Set<Integer> numbers = new TreeSet<Integer>();  
Set<String> words = new HashSet<String>();
```

The "for each" loop (7.1)

```
for (type name : collection) {  
    statements;  
}
```

- Provides a clean syntax for looping over the elements of a Set, List, array, or other collection

```
Set<Double> grades = new HashSet<Double>();
```

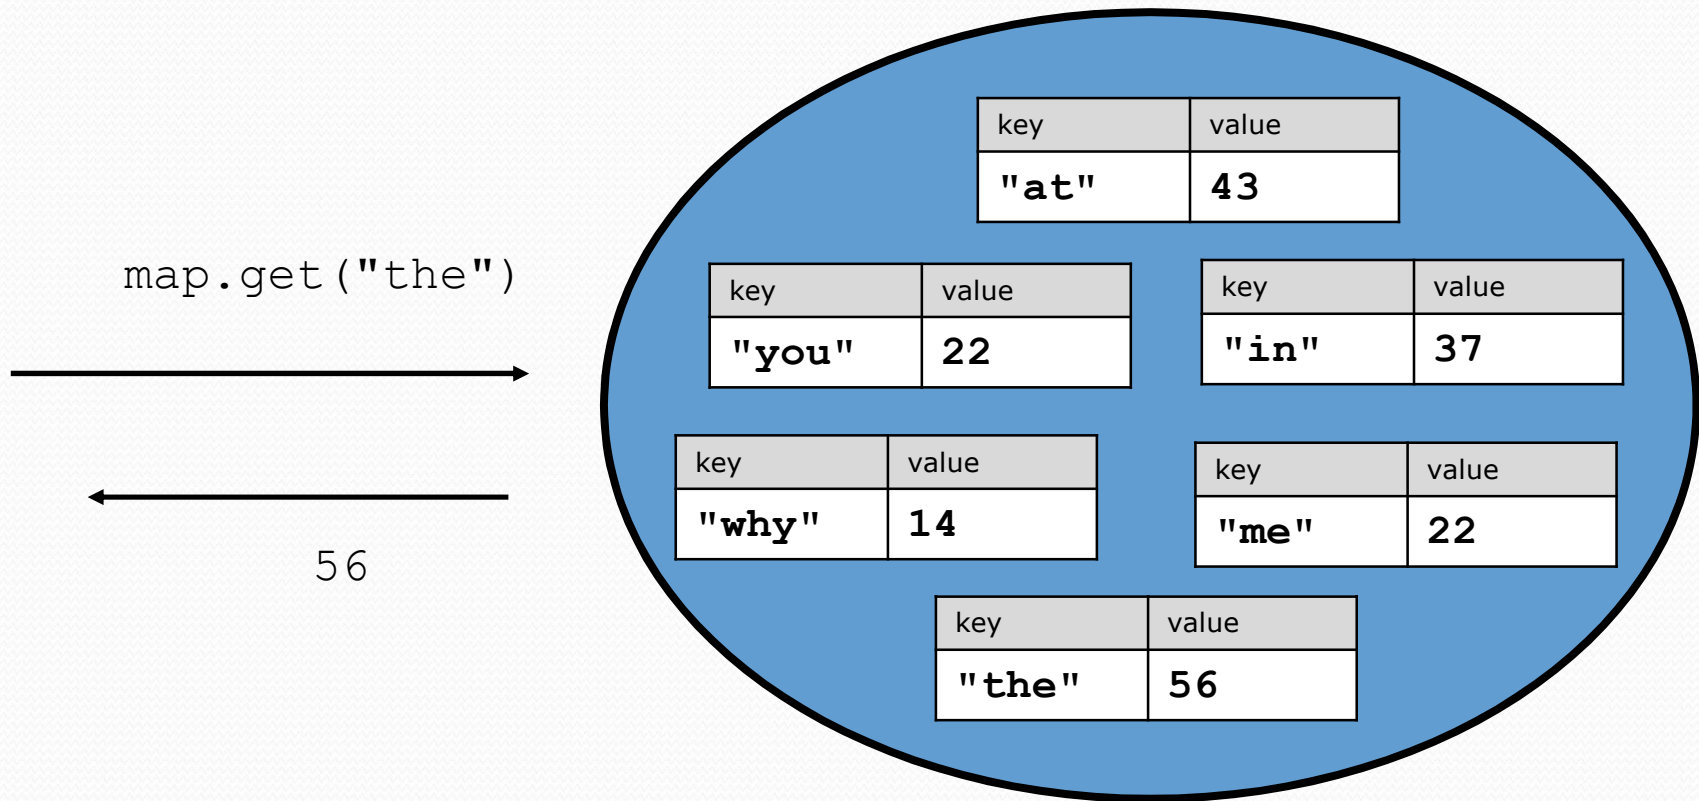

```
...
```

```
for (double grade : grades) {  
    System.out.println("Student's grade: " + grade);  
}
```

- needed because sets have no indexes; can't get element *i*

Maps (11.3)

- **map**: Holds a set of key-value pairs, where each key is unique
a.k.a. "dictionary", "associative array", "hash"

Maps (11.3)

- **map**: Holds a set of unique *keys* and a collection of *values*, where each key is associated with one value.
 - a.k.a. "dictionary", "associative array", "hash"
- basic map operations:
 - **put**(*key*, *value*): Adds a mapping from a key to a value.
 - **get**(*key*): Retrieves the value mapped to the key.
 - **remove**(*key*): Removes the given key and its mapped value.

	KEYS	VALUES	
	Jan	327.2	
	Feb	368.2	
	Mar	197.6	
	Apr	178.4	
	May	100.0	
	Jun	69.9	
	Jul	32.3	
Aug →	Aug	37.3	→ 37.3
	Sep	19.0	
	Oct	37.0	
	Nov	73.2	
	Dec	110.9	
	Annual	1551.0	

`myMap.get("Aug")` returns 37.3

Using maps

- A map allows you to get from one half of a pair to the other.
 - Remembers one piece of information about every index (key).

```
// key value  
put("Suzy", "206-685-2181")
```

- Later, we can supply only the key and get back the related value:

Allows us to ask: *What is Suzy's phone number?*

```
get("Suzy")  
"206-685-2181"
```

Map implementation

- Java provides the `Map` interface in `java.util`
- `Map` is implemented by the `HashMap` and `TreeMap` classes
 - `HashMap`: implemented using a "hash table"; extremely fast: keys are stored in unpredictable order
 - `TreeMap`: implemented as a linked "binary tree" structure; very fast: keys are stored in sorted order
- Maps require 2 type params: one for keys, one for values.

```
// maps from String keys to Integer values
```

```
Map<String, Integer> votes = new HashMap<String, Integer>();
```

```
// maps from Integer keys to String values
```

```
Map<Integer, String> words = new TreeMap<Integer, String>();
```

Map methods

<code>put(key, value)</code>	adds a mapping from the given key to the given value; if the key already exists, replaces its value with the given one
<code>get(key)</code>	returns the value mapped to the given key (<code>null</code> if not found)
<code>containsKey(key)</code>	returns <code>true</code> if the map contains a mapping for the given key
<code>remove(key)</code>	removes any existing mapping for the given key
<code>clear()</code>	removes all key/value pairs from the map
<code>size()</code>	returns the number of key/value pairs in the map
<code>isEmpty()</code>	returns <code>true</code> if the map's size is 0
<code>toString()</code>	returns a string such as <code>"{a=90, d=60, c=70}"</code>
<code>keySet()</code>	returns a set of all keys in the map
<code>values()</code>	returns a collection of all values in the map
<code>putAll(map)</code>	adds all key/value pairs from the given map to this map
<code>equals(map)</code>	returns <code>true</code> if given map has the same mappings as this one

keySet and values

- `keySet` method returns a `Set` of all keys in the map
 - can loop over the keys in a for-each loop
 - can get each key's associated value by calling `get` on the map

```
Map<String, Integer> ages = new TreeMap<String, Integer>();
ages.put("Marty", 19);
ages.put("Geneva", 2);
ages.put("Vicki", 57); // ages.keySet() returns Set<String>
for (String name : ages.keySet()) { // Geneva -> 2
    int age = ages.get(name); // Marty -> 19
    System.out.println(name + " -> " + age); // Vicki -> 57
}
```

- `values` method returns a collection of all values in the map
 - can loop over the values in a foreach loop
 - no easy way to get from a value to its associated key(s)
