

## Section 7: PHP

Due Date: Tuesday, November 7th

## 0. Two is Better Than One

Write a PHP function that takes a parameter word (called with a `$_GET` parameter passed in) and outputs its stuttered form in HTML. A stuttered word has each of its characters duplicated once, maintaining character order from the original word.

**Example:**

```
1 stutter("pikachu");  
2 stutter("aLAKaZAM");
```

Should produce the following output:

```
1 Your word stuttered is: ppiikkaacchhuu  
2 Your word stuttered is: aaLLAAkkaaZZAAMM
```

You should write your solution as if it were inside of your HTML page's body. In addition to writing `stutter`, you should provide an example call to the method, passing in the query parameter, where the url query should be "word=". In the first example where "pikachu" is passed as a parameter, the url would be in the form: `http://somebaseurl.php?word=pikachu`. If the query is absent from the url, then nothing should be output in the method.
