

# CSE 154

## LECTURE 23:RELATIONAL DATABASES AND SQL

# Relational databases

---

- **relational database**: A method of structuring data as tables associated to each other by shared attributes.
- a table row corresponds to a unit of data called a **record**; a column corresponds to an attribute of that record
- relational databases typically use **Structured Query Language (SQL)** to define, manage, and search data

# Why use a database?

---

- **powerful**: can search it, filter data, combine data from multiple sources
- **fast**: can search/filter a database very quickly compared to a file
- **big**: scale well up to very large data sizes
- **safe**: built-in mechanisms for failure recovery (e.g. **transactions**)
- **multi-user**: concurrency features let many users view/edit data at same time
- **abstract**: provides layer of abstraction between stored data and app(s)
  - many database programs understand the same SQL commands

# Database software

---

- Oracle
- Microsoft SQL Server (powerful) and Microsoft Access (simple)
- PostgreSQL (powerful/complex free open-source database system)
- SQLite (transportable, lightweight free open-source database system)
- MySQL (simple free open-source database system)
  - many servers run "LAMP" (Linux, Apache, MySQL, and PHP)
  - Wikipedia is run on PHP and MySQL
  - we will use MySQL in this course

# Example simpsons database

id	name	email
123	Bart	bart@fox.com
456	Milhouse	milhouse@fox.com
888	Lisa	lisa@fox.com
404	Ralph	ralph@fox.com
id	name	
1234	Krabappel	
5678	Hoover	
9012	Obourn	
student_id	course_id	grade
123	10001	B-
123	10002	C
456	10001	B+
888	10002	A+
888	10003	A+
404	10004	D+

**students**

**teachers**

**courses**

**grades**

- to test queries on this database, use username `homer`, password `d0ughnut`

# Example world database

code	name	continent	independence_year	population	gnp	head_of_state	...
AFG	Afghanistan	Asia	1919	22720000	5976.0	Mohammad Omar	...
NLD	Netherlands	Europe	1581	15864000	371362.0	Beatrix	...
...	...	...	...	...	...	...	...

**countries** (Other columns: region, surface\_area, life\_expectancy, gnp\_old, local\_name, government\_form, capital, code2)

id	name	country_code	district	population
3793	New York	USA	New York	8008278
1	Los Angeles	USA	California	3694820
...	...	...	...	...

**cities**

- to test queries on this database, use username **traveler**, password **packmybags**

country_code	language	official	percentage
AFG	Pashto	T	52.4
NLD	Dutch	T	95.6
...	...	...	...

**languages**

# Example imdb database

id	first_name	last_name	gender	id	name	year	rank	actor_id	movie_id	role
433259	William	Shatner	M	112290	Fight Club	1999	8.5	433259	313398	Capt. James T. Kirk
797926	Britney	Spears	F	209658	Meet the Parents	2000	7	433259	407323	Sgt. T.J. Hooker
831289	Sigourney	Weaver	F	210511	Memento	2000	8.7	797926	342189	Herself
...										

actors

movie_id	genre
209658	Comedy
313398	Action
313398	Sci-Fi
...	

movies\_genres

movies

id	first_name	last_name
24758	David	Fincher
66965	Jay	Roach
72723	William	Shatner
...		

directors

actor_id	movie_id	role
433259	313398	Capt. James T. Kirk
433259	407323	Sgt. T.J. Hooker
797926	342189	Herself
...		

roles

director_id	movie_id
24758	112290
66965	209658
72723	313398
...	

movies\_directors

- also available, `imdb_small` with fewer records (for testing queries)
- to test queries on this database, use the username/password that we will email to you soon

# SQL basics

```
SELECT name FROM cities WHERE id = 17;
```

SQL

```
INSERT INTO countries VALUES ('SLD', 'ENG', 'T', 100.0);
```

SQL

- **Structured Query Language (SQL):** a language for searching and updating a database
- a standard syntax that is used by all database software (with minor incompatibilities)
  - generally case-insensitive
- a **declarative** language: describes what data you are seeking, not exactly how to find it

# The SQL SELECT statement

```
SELECT column(s) FROM table;
```

SQL

```
SELECT name, code FROM countries;
```

SQL

name	code
China	CHN
United States	IND
Indonesia	USA
Brazil	BRA
Pakistan	PAK
...	...

- the **SELECT** statement searches a database and returns a set of results
- the column name(s) written after **SELECT** filter which parts of the rows are returned
- table and column names are case-sensitive

# The DISTINCT modifier

```
SELECT DISTINCT column(s) FROM table;
```

PHP

- eliminates duplicates from the result set

```
SELECT language  
FROM languages;
```

SQL

language
Dutch
English
English
Papiamento
Spanish
Spanish
Spanish
...

```
SELECT DISTINCT language  
FROM languages;
```

SQL

language
Dutch
English
Papiamento
Spanish
...

# The WHERE clause

```
SELECT column(s) FROM table WHERE condition(s);
```

SQL

```
SELECT name, population FROM cities WHERE country_code = "FSM";
```

name	population
Weno	22000
Palikir	8600

- WHERE clause filters out rows based on their columns' data values
- in large databases, it's critical to use a WHERE clause to reduce the result set size
- suggestion: when trying to write a query, think of the FROM part first, then the WHERE part, and lastly the SELECT part

# More about the WHERE clause

WHERE column operator value(s)	SQL
SELECT name, gnp FROM countries WHERE gnp > 2000000;	SQL

- the WHERE portion of a SELECT statement can use the following operators:
  - =, >, >=, <, <=
  - <> : not equal
  - BETWEEN *min* AND *max*
  - LIKE *pattern*
  - IN (*value, value, ..., value*)

code	name	gnp
JPN	Japan	3787042.00
DEU	Germany	2133367.00
USA	United States	8510700.00
...	...	...

# Multiple WHERE clauses: AND, OR

```
SELECT * FROM cities WHERE code = 'USA' AND population >= 2000000;
```

id	name	country_code	district	population
3793	New York	USA	New York	8008278
3794	Los Angeles	USA	California	3694820
3795	Chicago	USA	Illinois	2896016
...	...	...	...	...

- multiple WHERE conditions can be combined using AND and OR

# Approximate matches: LIKE

```
WHERE column LIKE pattern
```

SQL

```
SELECT code, name, population FROM countries WHERE name  
LIKE 'United%';
```

SQL

code	name	population
ARE	United Arab Emirates	2441000
GBR	United Kingdom	59623400
USA	United States	278357000
UMI	United States Minor Outlying Islands	0

- `LIKE 'text%`' searches for text that starts with a given prefix
- `LIKE '%text'` searches for text that ends with a given suffix
- `LIKE '%text%'` searches for text that contains a given substring

# Sorting by a column: ORDER BY

ORDER BY column(s)

SQL

```
SELECT code, name, population FROM countries  
WHERE name LIKE 'United%' ORDER BY population;
```

SQL

code	name	population
UMI	United States Minor Outlying Islands	0
ARE	United Arab Emirates	2441000
GBR	United Kingdom	59623400
USA	United States	278357000

- can write ASC or DESC to sort in ascending (default) or descending order:

```
SELECT * FROM countries  
ORDER BY population  
DESC;
```

SQL

- can specify multiple orderings in decreasing order of significance:

```
SELECT * FROM countries ORDER BY population DESC, gnp; SQL
```

# Limiting rows: LIMIT

```
LIMIT number
```

[SQL](#)

```
SELECT name FROM cities WHERE name LIKE 'K%' LIMIT 5; SQL
```

name
Kabul
Khulna
Kingston upon Hull
Koudougou
Kafr al-Dawwar

- can be used to get the top-N of a given category (`ORDER BY` and `LIMIT`)
- also useful as a sanity check to make sure your query doesn't return  $10^7$  rows

# Querying a Database in PHP with PDO

```
$name = new PDO("dbprogram:dbname=database;host=server",
username, password);
$name->query("SQL query");
```

PHP

```
# connect to world database on local server
$db = new PDO("mysql:dbname=world;host=localhost",
"traveler", "packmybags");
$db->query("SELECT * FROM countries WHERE population >
100000000");
```

- PDO database library allows you to connect to many different database programs
  - replaces older, less versatile functions like `mysql_connect`
  - PDO object's `query` function returns rows that match a query

# Result rows: query

```
$db = new PDO("dbprogram:dbname=database;host=server",  
username, password);  
$rows = $db->query("SQL query");  
foreach ($rows as $row) {  
    do something with $row;  
}
```

PHP

- query returns all result rows
  - each row is an associative array of [column name -> value]
  - example: `$row["population"]` gives the value of the population column

# A complete example

```
$db = new PDO("mysql:dbname=imdb_small", "jessica",
"guinness");
$rows = $db->query("SELECT * FROM actors WHERE last_name
LIKE 'Del%'");
foreach ($rows as $row) {
    ?>
<li> First name: <?= $row["first_name"] ?>,
    Last name: <?= $row["last_name"] ?> </li>
<?php
}
```

PHP

- First name: Benicio, Last name: Del Toro
- First name: Michael, Last name: Delano
- ...

output

# Including variables in a query

```
# get query parameter for name of movie
$title = $_GET["movietitle"];
$rows = $db->query("SELECT year FROM movies
WHERE name = '$title'");
```

PHP

- you should not directly include variables or query parameters in a query
- they might contain illegal characters or SQL syntax to mess up the query

# Quoting variables

```
# get query parameter for name of movie
$title = $_GET["movietitle"];
$title = $db->quote($title);
$rows = $db->query("SELECT year FROM movies WHERE name =
$title");
```

PHP

- call PDO's quote method on any variable to be inserted
- quote escapes any illegal chars and surrounds the value with ' quotes
- prevents bugs and security problems in queries containing user input

# Database/query errors

---

```
$db = new PDO("mysql:dbname=imdb_small", "jessica", "guinness");
$rows = $db->query("SEEELECT * FROM movies WHERE year = 2000");
# FALSE
```

PHP

- database commands can often fail (invalid query; server not responding; etc.)
- normally, PDO commands fail silently by returning **FALSE** or **NULL**
- but this makes it hard to notice and handle problems

# Exceptions for errors

---

```
$db = new PDO("mysql:dbname=imdb_small", "jessica", "guinness");
$db->setAttribute(PDO::ATTR_ERRMODE, PDO::ERRMODE_EXCEPTION);
$rows = $db->query("SEEELECT * FROM movies WHERE year = 2000");
                                # kaboom!
```

PHP

- using `setAttribute`, you can tell PDO to throw (generate) a `PDOException` when an error occurs
- the exceptions will appear as error messages on the page output
- you can `catch` the exception to gracefully handle the error

# Catching an exception

---

```
try {  
    statement(s);  
} catch (ExceptionType $name) {  
    code to handle the error;  
}
```

PHP

- a **try/catch** statement attempts to run some code, but if it throws a given kind of exception, the program jumps to the **catch** block and runs that code to handle the error

# Example with error checking

```
try {
    $db = new PDO("mysql:dbname=imdb_small", "jessica",
                  "guinness");
    $db->setAttribute(PDO::ATTR_ERRMODE, PDO::ERRMODE_EXCEPTION);
    $rows = $db->query("SEEELECT * FROM movies WHERE year = 2000");
    foreach ($rows as row) { ... }
} catch (PDOException $ex) {
    ?>
    <p>Sorry, a database error occurred. Please try again later.
    </p>
    <p>(Error details: <?= $ex->getMessage() ?>)</p>
    <?php
}
```

PHP

# PDOStatement methods

The `$rows` variable returned by PDO's `query` method is technically not an array but an object of type `PDOStatement`. It can be `foreach`-ed over like an array, but it also has the following methods:

<a href="#"><u>columnCount()</u></a>	number of columns in the results
<a href="#"><u>fetch()</u></a>	return the next row from the results
<a href="#"><u>fetchColumn(<i>number</i>)</u></a>	return the next column from the results
<a href="#"><u>rowCount()</u></a>	number of rows returned by the query

```
if ($db->rowCount() > 0) {  
    $first_row = $db->fetch();  
    ...  
}
```

PHP
