QuickCheck 7: PHP Web Service

Due Date: Tuesday, May 8

0. Two is Better Than One!

Write a PHP function called `stutter` that takes a parameter `$word` and prints its stuttered form. A stuttered word has each of its characters duplicated once, maintaining character order from the original word.

Example:

```
1  stutter("pikachu");
2  stutter("aLAkaZAM");
```

Should produce the following output:

```
1  Your word stuttered is: ppiikkaacchhuu
2  Your word stuttered is: aaLLAAkkaaZZAAMM
```

After writing the function, call it by passing in a `GET` parameter called `word`. In the first example where "pikachu" is passed as a parameter, the url would be in the form: `http://somebaseurl.php?word=pikachu`.

If the query is absent from the url, then nothing should be output.
