Winter 2017

What is a list?

A list is an ordered sequence of values

- What operations should a list support efficiently and conveniently?
 - Creation
 - Querying
 - Modification

List creation

$$c = [4, 'a', a]$$

b = [5, 3, 'hi']

$$d = [[1, 2], [3, 4], [5, 6]]$$

List Querying

- Extracting part of the list:
 - Single element: mylist[index]
 - Sublist ("slicing"): mylist[startidx : endidx]
- Find/lookup in a list
 - -elt in mylist
 - Evaluates to a boolean value
 - mylist.index(x)
 - Return the int index in the list of the first item whose value is x. It is an error if there is no such item.
 - mylist.count(x)
 - Return the number of times x appears in the list.

List Modification

- Insertion
- Removal
- Replacement
- Rearrangement

List Insertion

- mylist.append(x)
 - Extend the list by inserting x at the end
- mylist.extend(L)
 - Extend the list by appending all the items in the argument list
- mylist.insert(i, x)
 - Insert an item before the a given position.
 - a.insert(0, x) inserts at the front of the list

List Removal

- mylist.remove(x)
 - Remove the first item from the list whose value is x
 - It is an error if there is no such item
 - Returns None

Notation from the Python Library Reference:
The square brackets around the parameter, "[i]",
means the argument is *optional*.
It does *not* mean you should type square brackets
at that position.

- mylist.pop([i])
 - Remove the item at the given position in the list, and return it.
 - If no index is specified, a.pop() removes and returns the last item in the list.

List Replacement

- mylist[index] = newvalue
- mylist[start:end] = newsublist
 - Can change the length of the list
 - mylist[start:end] = [] removes multiple
 elements
 - -a[len(a):] = L is equivalent to a.extend(L)

List Rearrangement

- list.sort()
 - Sort the items of the list, in place.
 - "in place" means by modifying the original list, not by creating a new list.
- list.reverse()
 - Reverse the elements of the list, in place.

How to evaluate a list expression

There are two new forms of expression:

- [a, b, c, d]
- list creation
- To evaluate:
 - evaluate each element to a value, from left to right
 - make a list of the values

Same tokens "[]" with two distinct meanings

- The elements can be arbitrary values, including lists
 - ["a", 3, 3.14 * r * r, fahr_to_cent(-40), [3 + 4, 5 * 6]]

expression

List

list indexing or dereferencing

Index expression

To evaluate:

- evaluate the list expression to a value
- evaluate the index expression to a value
- if the list value is not a list, execution terminates with an error
- if the element is not in range (not a valid index), execution terminates with an error
- the value is the given element of the list value (counting from zero)

List expression examples

What does this mean (or is it an error)?

```
["four", "score", "and", "seven", "years"][2]
["four", "score", "and", "seven", "years"][0,2,3]
["four", "score", "and", "seven", "years"][[0,2,3]]
["four", "score", "and", "seven", "years"][[0,2,3][1]]
```

Exercise: list lookup

```
def index(somelist, value):
  """Return the position of the first
occurrence of the element value in the
list somelist.
Return None if value does not appear in
somelist."""
Examples:
   gettysburg = ["four", "score", "and", "seven",
   "years", "ago"]
   index(gettysburg, "and") => 2
   index(gettysburg, "years") => 4
Fact: mylist[index(mylist, x)] == x
```

Exercise: list lookup (Answer #1)

```
def index(somelist, value):
  """Return the position of the first
occurrence of the element value in the
list somelist.
Return None if value does not appear in
somelist."""
  i = 0
  for c in somelist:
    if c == value:
      return i
    i = i + 1
  return None
```

Exercise: list lookup (Answer #2)

```
def index(somelist, value):
  """Return the position of the first
occurrence of the element value in the
list somelist.
Return None if value does not appear in
somelist."""
for i in range(len(somelist)):
    if somelist[i] == value:
      return i
return None
```

Exercise: Convert Units

```
ctemps = [-40, 0, 20, 37, 100]
# Goal: set ftemps to [-40, 32, 68, 98.6, 212]
# Assume a function celsius_to_fahrenheit exists
ftemps = []
```

Exercise: Convert Units (Answer)

```
ctemps = [-40, 0, 20, 37, 100]
# Goal: set ftemps to [-40, 32, 68, 98.6, 212]
# Assume a function celsius_to_fahrenheit exists
ftemps = []
for c in ctemps:
    f = celsius_to_farenheit(c)
    ftemps.append(f)
```

List Slicing

mylist[startindex:endindex] evaluates to a sublist of the original list

- mylist[index] evaluates to an element of the original list
- Arguments are like those to the range function
 - mylist[start:end:step]
 - start index is inclusive, end index is exclusive
 - All 3 indices are optional
- Can assign to a slice: mylist[s:e] = yourlist

List Slicing Examples

```
test list = ['e0', 'e1', 'e2', 'e3', 'e4', 'e5', 'e6']
                     From e2 to the end of the list:
                         test list[2:]
              From beginning up to (but not including) e5:
                          test list[:5]
                            Last element:
                          test list[-1]
                         Last four elements:
                         test list[-4:]
                 Everything except last three elements:
                         test list[:-3]
                           Reverse the list:
                        test list[::-1]
                      Get a copy of the whole list:
                          test list[:]
```
