# Making decisions

- How do we compute absolute value?

Absolute value of        5      is

Absolute value of        0      is

Absolute value of        -22     is

If the value is negative, negate it.

Otherwise, use the original value.

# Absolute value solution

**If** the value is negative, negate it.

**Otherwise**, use the original value.

```
val = -10
# calculate absolute value of val
if val < 0:
    result = -val
else:
    result = val
print(result)
```

Condition must be a Boolean expression

Indentation is significant

else is not required

In this example, **result** will always be assigned a value.

# Absolute value solution

If the value is negative, negate it.

Otherwise, use the original value.

```
val = -10

# calculate absolute value of val
if val < 0:
    result = -val
else:
    result = val

print(result)
```

Another approach  
that does the same thing  
without using `result`:

```
val = -10

if val < 0:
    print(-val)
else:
    print(val)
```

In this example, `result` will always be assigned a value.

# Absolute value solution

As with loops, a sequence of statements could be used in place of a single statement:

```
val = -10

# calculate absolute value of val
if val < 0:
    result = -val
    print("val is negative!")
    print("I had to do extra work!")
else:
    result = val
    print("val is positive")
print(result)
```

# Absolute value solution with zero

```
val = 0

# calculate absolute value of val
if val < 0:
    print("val is negative")
    print(val)
    result = -val
elif val == 0:
    print("val is zero")
    print(val)
    result = val
else:
    print("val is positive")
    print(val)
    result = val

print(result)
```

# Another absolute value solution

What happens here?

```
val = 5

# calculate absolute value of val
if val < 0:
    result = -val
    print("val is negative!")
else:
    for i in range(val):
        print("val is positive!")
    result = val
print(result)
```

# Another if

It is not required that anything happens...

```
val = -10

if val < 0:
    print("negative value!")
```

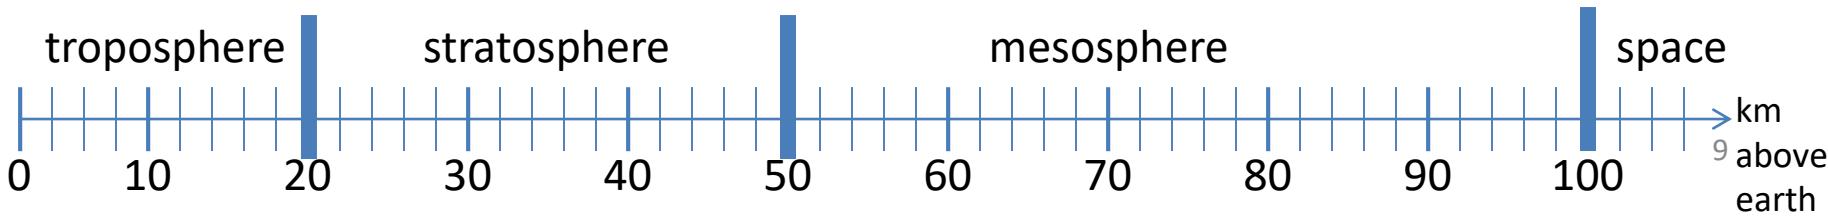

What happens when val = 5?

# The if body can be any statements

```
# height is in km  
if height > 100:  
    print("space")  
  
then clause {  
    else:  
        if height > 50:  
            print("mesosphere")  
        else:  
            if height > 20:  
                print("stratosphere")  
            else:  
                print("troposphere")  
  
else clause {  
    else:  
        if height > 50:  
            print("space")  
        elif height > 20:  
            print("mesosphere")  
        else:  
            print("stratosphere")  
            if height > 20:  
                print("stratosphere")  
            else:  
                print("troposphere")  
  
else:  
    print("troposphere")
```

Execution gets here only if "height > 100" is false

Execution gets here only if "height > 50" is false AND "height > 20" is true

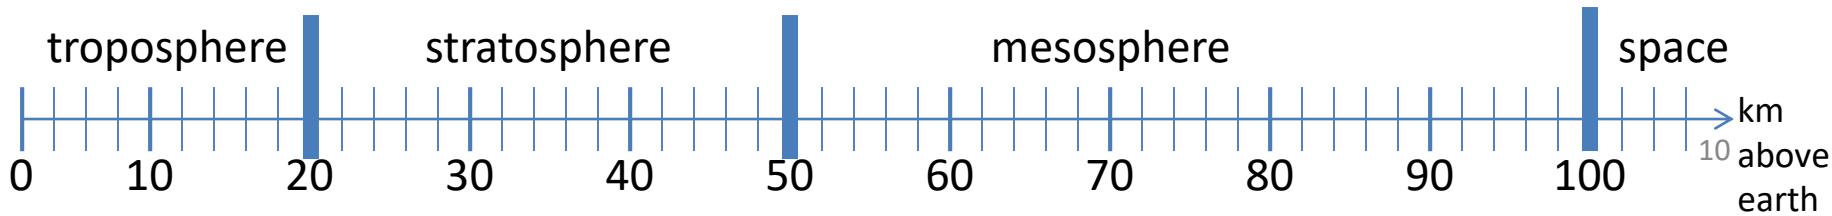

# Version 1

```
# height is in km
if height > 100:
    then clause { print("space") }
else:
    if height > 50:
        t{ print("mesosphere") }
    else:
        if height > 20:
            t{ print("stratosphere") }
        else:
            e{ print("troposphere") }
```

Execution gets here only if "height <= 100" is true

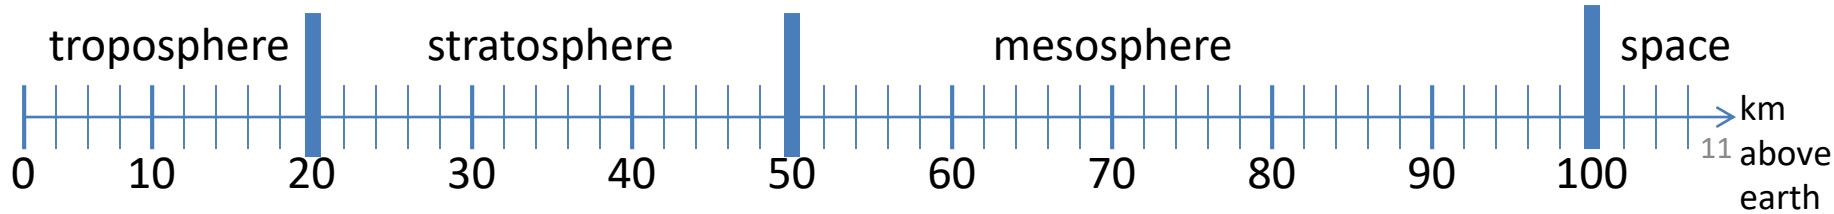

Execution gets here only if "height <= 100" is true AND "height > 50" is true

[See in python tutor](#)

# Version 1

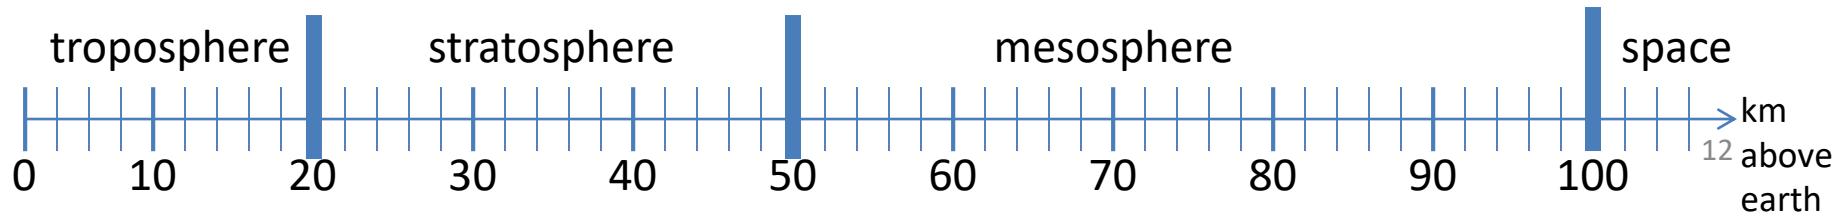

```
# height is in km
if height > 100:
    print("space")
else:
    if height > 50:
        print("mesosphere")
    else:
        if height > 20:
            print("stratosphere")
        else:
            print("troposphere")
```

[See in python tutor](#)

# Version 2

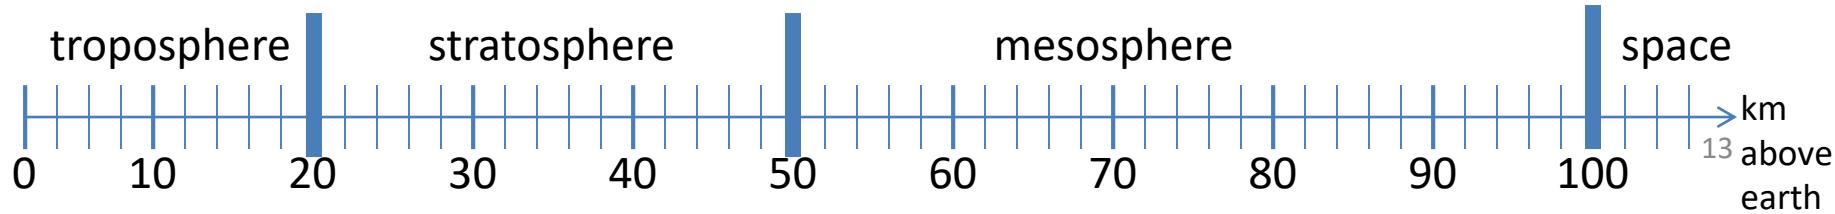

```
if height > 50:  
    if height > 100:  
        print("space")  
    else:  
        print("mesosphere")  
else:  
    if height > 20:  
        print("stratosphere")  
    else:  
        print("troposphere")
```

# Version 3 (Best)

```
if height > 100:  
    print("space")  
elif height > 50:  
    print("mesosphere")  
elif height > 20:  
    print("stratosphere")  
else:  
    print("troposphere")
```

ONE of the print statements is guaranteed to execute:  
whichever condition it encounters first that is true

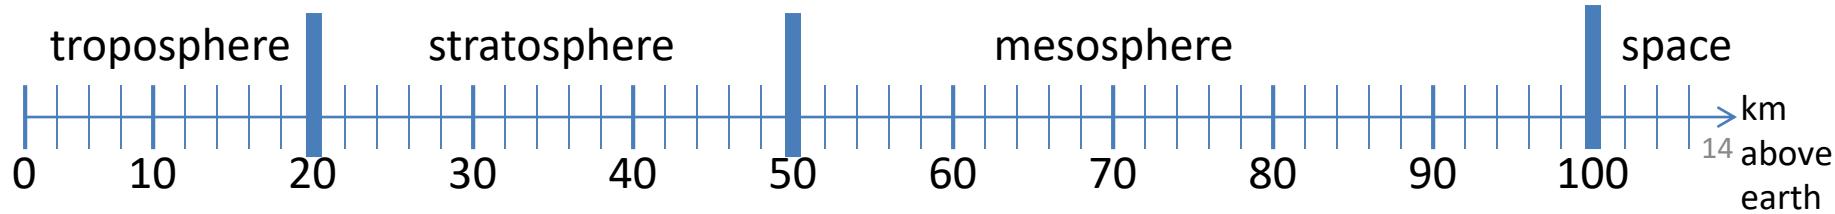

[See in python tutor](#)

# Order Matters

```
# version 3
if height > 100:
    print("space")
elif height > 50:
    print("mesosphere")
elif height > 20:
    print("stratosphere")
else:
    print("troposphere")
```

```
# broken version 3
if height > 20:
    print("stratosphere")
elif height > 50:
    print("mesosphere")
elif height > 100:
    print("space")
else:
    print("troposphere")
```

Try height = 72 on both versions, what happens?

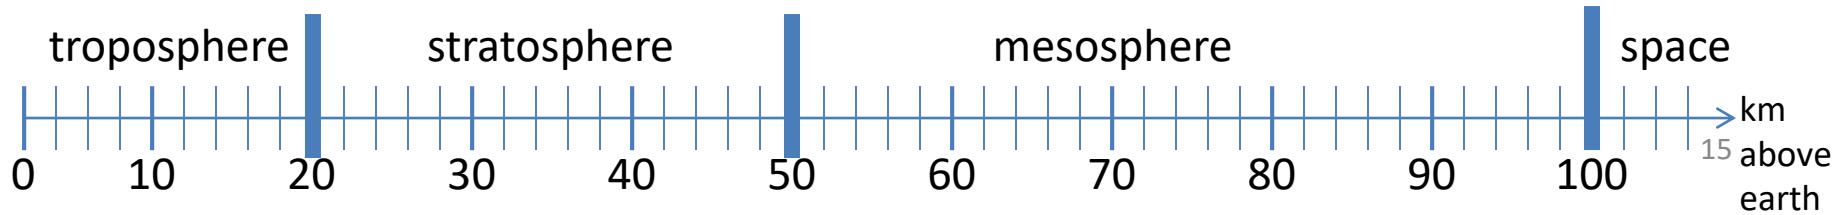

[See in python tutor](#)

# Incomplete Version 3

```
# incomplete version 3
if height > 100:
    print("space")
elif height > 50:
    print("mesosphere")
elif height > 20:
    print("stratosphere")
```

In this case it is possible that nothing is printed at all, when?

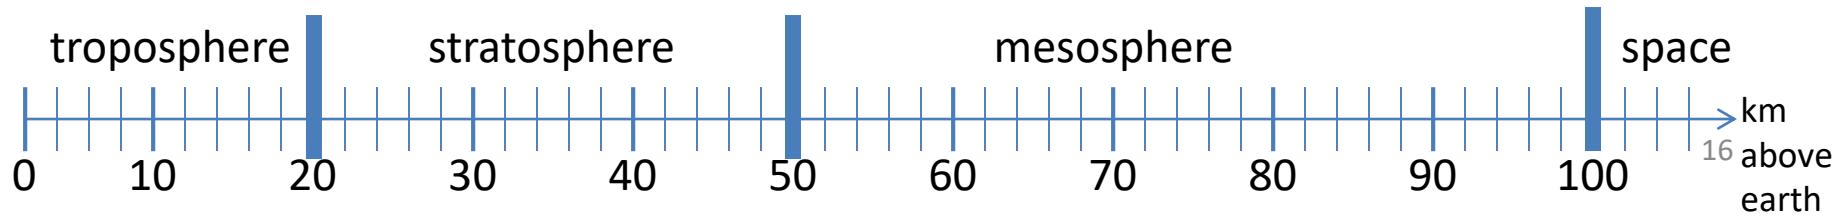

[See in python tutor](#)

# What Happens Here?

```
# height is in km
if height > 100:
    print("space")
if height > 50:
    print("mesosphere")
if height > 20:
    print("stratosphere")
else:
    print("troposphere")
```

Try height = 72

# The then clause *or* the else clause is executed

[See in python tutor](#)

```
speed = 54
limit = 55
if speed <= limit:
    print("Good job!")
else:
    print("You owe $", speed/fine)
```

What if we change speed to 64?
