## Last lecture highlights

Finite State Machines with output at states

State minimization

$\Rightarrow$

## Last lecture highlights

Lemma: The language recognized by a DFA is the set of strings $x$ that label some path from its start state to one of its final states

## Nondeterministic Finite Automaton (NFA)

- Graph with start state, final states, edges labeled by symbols (like DFA) but
- Not required to have exactly 1 edge out of each state labeled by each symbol - can have 0 or >1
- Also can have edges labeled by empty string $\lambda$

Definition: The language recognized by an NFA is the set of strings $x$ that label some path from its start state to one of its final states

## Three ways of thinking about NFAs

- Outside observer: Is there a path labeled by $x$ from the start state to some final state?
- Perfect guesser: The NFA has input $x$ and whenever there is a choice of what to do it magically guesses a good one (if one exists)
- Parallel exploration: The NFA computation runs all possible computations on $x$ step-bystep at the same time in parallel

Design an NFA with 4 states to recognize the set of binary strings whose $3^{\text {rd }}$ from last character is a 1

Design an NFA to recognize the set of binary strings that contain 111 or have an even \# of 1's

## NFAs and Regular Expressions

Theorem: For any set of strings (language) A described by a regular expression, there is an NFA that recognizes A.

Proof idea: Structural induction based on the recursive definition of regular expressions...

Note: One can also find a regular expression to describe the language recognized by any NFA but we won't prove that fact

## Regular expressions over $\Sigma$

- Basis:
$-\varnothing, \lambda$ are regular expressions
$-\boldsymbol{a}$ is a regular expression for any $a \in \Sigma$
- Recursive step:
- If $\mathbf{A}$ and $\mathbf{B}$ are regular expressions then so are:
- $(A \cup B)$
- (AB)
- $A^{*}$

## Basis

- Case Ø:
- Case $\lambda$ :
- Case $\boldsymbol{a}$ :

Basis

- Case $\varnothing$ :
- Case $\lambda$ :
- Case $\boldsymbol{a}$ :

## Inductive Hypothesis

- Suppose that for some regular expressions $\mathbf{A}$ and $\mathbf{B}$ there exist NFAs $\mathrm{N}_{\mathrm{A}}$ and $\mathrm{N}_{\mathrm{B}}$ such that $N_{A}$ recognizes the language given by $A$ and $N_{B}$ recognizes the language given by $\mathbf{B}$

Inductive Step

- Case $(\mathbf{A} \cup \mathbf{B})$ :

- Case $(\mathbf{A} \cup \mathbf{B})$ :

## Inductive Step

$\mathrm{N}_{\mathrm{B}}$

## Inductive Step

- Case (AB):

Inductive Step

- Case (AB):

- Case A*

Inductive Step

Build a NFA for $(01 \cup 1)^{*} 0$

## Solution

$(01 \cup 1) * 0$

## NFAs and DFAs

Every DFA is an NFA

- DFAs have requirements that NFAs don't have

Can NFAs recognize more languages? No!

Theorem: For every NFA there is a DFA that recognizes exactly the same language

## Conversion of NFAs to a DFAs

- Proof Idea:
- The DFA keeps track of ALL the states that the part of the input string read so far can reach in the NFA
- There will be one state in the DFA for each subset of states of the NFA that can be reached by some string

## Conversion of NFAs to a DFAs

- New start state for DFA
- The set of all states reachable from the start state of the NFA using only edges labeled $\lambda$

NFA

DFA

## Conversion of NFAs to a DFAs

- For each state of the DFA corresponding to a set S of states of the NFA and each symbol s
- Add an edge labeled $s$ to state corresponding to $T$, the set of states of the NFA reached by
- starting from some state in S, then
- following one edge labeled by s, and
- then following some number of edges labeled by $\lambda$
$-T$ will be $\varnothing$ if no edges from $S$ labeled s exist

## Example: NFA to DFA

## Conversion of NFAs to a DFAs

- Final states for the DFA
- All states whose set contain some final state of the NFA

a,b,c,e

DFA

## Exponential blow-up in simulating

 nondeterminism- In general the DFA might need a state for every subset of states of the NFA
- Power set of the set of states of the NFA
- n-state NFA yields DFA with at most $2^{n}$ states
- We saw an example where roughly $2^{n}$ is necessary
- Is the $\mathrm{n}^{\text {th }}$ char from the end a 1 ?
- The famous "P=NP?" question asks whether a similar blow-up is always necessary to get rid of nondeterminism for polynomial-time algorithms
