Inference rules for quantifiers

**Elim ∀**

\[ \forall x. P(x) \]
\[ \therefore P(a) \text{ for any } a \]

**Intro ∀**

\[ P(a); \text{ } a \text{ is arbitrary} \]
\[ \therefore \forall x. P(x) \]

**Intro ∃**

\[ \therefore \exists x. P(x) \]

**Elim ∃**

\[ \exists x. P(x) \]
\[ \therefore P(c) \text{ for a specific } c \]

The name \( a \) stands for an arbitrary value in the domain. No other name in \( P \) depends on \( a \).

The name \( c \) is **fresh** and stands for a value in the domain where \( P(c) \) is true. List all dependencies for \( c \).
Predicate logic proofs can use …

Predicate logic inference rules
   Applied to whole formulas only.

Predicate logic equivalences
   Even on subformulas.

Propositional logic inference rules
   Applied to whole formulas only.

Propositional logic equivalences

Natural language proofs

From formal proofs to natural language proofs.
Natural language versus (predicate) logic proofs

We often write proofs in English rather than as fully formal proofs. They are easier for people to read. (But theorem provers prefer fully formal proofs. :)

English proofs follow the structure of the corresponding formal proofs. Formal proof methods help to understand how proofs work in English. And they give clues for how to produce the proofs in English.

Let \( a \) be an arbitrary even integer.

Then, by definition, \( a = 2b \)

Proof strategies

Proof by contrapositive, counterexamples, and proof by contradiction.
Proof by contrapositive

If we assume \( \neg q \) and derive \( \neg p \), then we have proven that \( \neg q \rightarrow \neg p \), which is equivalent to proving \( p \rightarrow q \).

1.1. \( \neg q \)  
   **Assumption**

1.3. \( \neg p \)

2. \( \neg q \rightarrow \neg p \)  
   **Direct Proof Rule**

3. \( p \rightarrow q \)  
   **Contrapositive: 2**
Counterexamples

To *disprove* $\forall x. P(x)$, prove $\exists x. \neg P(x)$.

Works by DeMorgan’s Law: $\neg \forall x. P(x) \equiv \exists x. \neg P(x)$.

All we need to do is find an $x$ for which $P(x)$ is false.

This $x$ is called a *counterexample*.

Example: disprove that “Every prime number is odd”.
Counterexamples

To *disprove* \( \forall x. P(x) \), prove \( \exists x. \neg P(x) \).

Works by DeMorgan’s Law: \( \neg \forall x. P(x) \equiv \exists x. \neg P(x) \).

2 is a prime number that is not odd.

Fun fact: counterexamples & contradiction in verification

Automated verifiers work by counterexample and contradiction proofs.
Recall that program verification involves proving that a program $P$ satisfies a specification $S$ on all inputs $x$: $\forall x. p(x) \rightarrow s(x)$, where $p$ and $s$ are formulas encoding the semantics of $P$ and $S$.

The program verifier sends the formula \( \exists x. p(x) \land \neg s(x) \) to the prover.

\[

Summary

Formal (logic) proofs follow well-defined rules and are easy to check.
   They can be checked mechanically.
   And are used in the construction of critical software.

English proofs correspond to those rules but are easier for people to read.
   Easily checkable in principle.

Simple proof strategies already do a lot.
   Later we will cover a specific strategy that applies to loops and recursion
   (mathematical induction).
