- In principle, formal proofs are the standard for what it means to be "proven" in mathematics
 - almost all math (and theory CS) done in Predicate Logic
- But they are tedious and impractical
 - e.g., applications of commutativity and associativity
 - Russell & Whitehead's formal proof that 1+1 = 2 appears after more than 100 pages of build up
 - we allowed ourselves to cite "Arithmetic", "Algebra", etc.
- Similar situation exists in programming...

- Formal proofs follow simple well-defined rules and should be easy for a machine to check
 - as assembly language is easy for a machine to execute
- English proofs correspond to those rules but are designed to be easier for humans to read
 - also easy to check with practice

(almost all actual math and theory CS is done this way)

 English proof is correct if the <u>reader</u> is convinced that they could translate it into a formal proof
