CSE 311: Foundations of Computing

Final exam Monday, Review session Sunday

- Monday at either 2:30-4:20 or 4:30-6:20
 - JHN 102
 - Must select your exam time by Saturday
 No changes permitted after that
 - Bring your UW ID
- **Comprehensive:** Full probs only on topics that were covered in homework. May have small probs on other topics.
 - May includes pre-midterm topics, e.g., formal proofs.
 - Reference sheets will be included. Closed book. No notes.
- Review session: Sunday starting at 1 pm on Zoom — Bring your questions !!

A set **S** is **countable** iff we can order the elements of **S** as $S = \{x_1, x_2, x_3, ...\}$

Countable sets:

- $\mathbb N$ the natural numbers
- $\mathbb Z$ the integers \checkmark
- \mathbb{Q} the rationals \checkmark

 Σ^* - the strings over any finite $\Sigma
eq$ "dov

The set of all Java programs

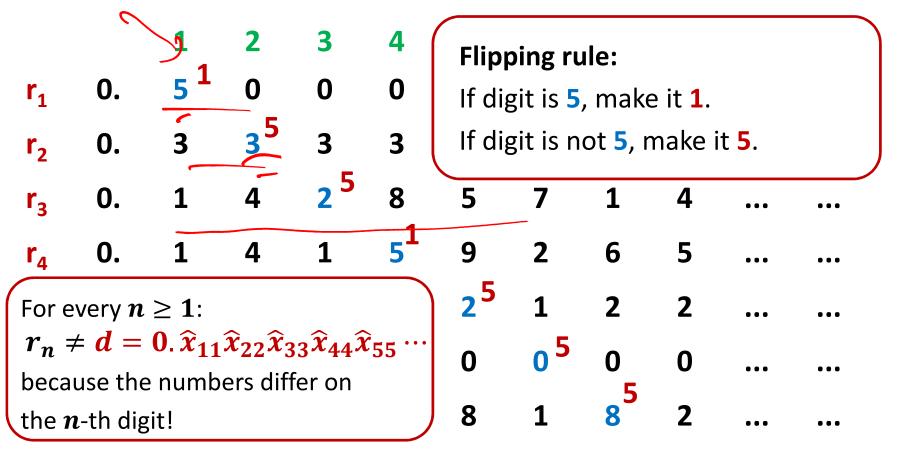

Shown by "dovetailing" **Theorem** [Cantor]:

The set of real numbers between 0 and 1 is **not** countable.

Proof using "diagonalization".

Last time: Proof that [0,1) is not countable

Suppose, for the sake of contradiction, that there is a list of them:

So the list is incomplete, which is a contradiction.

Thus the real numbers between 0 and 1 are not countable: "uncountable"

- The set of rational numbers in [0,1) also have decimal representations like this
 - The only difference is that rational numbers always have repeating decimals in their expansions 0.33333... or .25000000...
- So why wouldn't the same proof show that this set of rational numbers is uncountable?
 - Given any listing we could create the flipped diagonal number *d* as before
 - However, *d* would not have a repeating decimal expansion and so wouldn't be a rational #

It would not be a "missing" number, so no contradiction.

Last time: The set of all functions $f : \mathbb{N} \to \{0, ..., 9\}$ is uncountable

Supposed listing of all the functions:

	1	2	3	4	Flippi	ng rule	e:			
f ₁	5 ¹	0	0	0	If f_n			D (n)	= 1	
f ₂	3	3 ⁵	3	3	If f_n	$n) \neq !$	5, set	D(n)	= 5	J
f ₃	1	4	2 ⁵	8	5	7	1	4	•••	
f ₄	1	4	1	5 ¹	9	2	6	5	•••	•••
f ₅	1	2	1	2	2 ⁵	1	2	2	•••	•••
f ₆	2	5	0	0	0	0 ⁵	0	0	•••	•••
f ₇	7	1	8	2	8	1	8	2	•••	•••

For all n, we have $D(n) \neq f_n(n)$. Therefore $D \neq f_n$ for any n and the list is incomplete! $\Rightarrow \{f \mid f : \mathbb{N} \rightarrow \{0, 1, \dots, 9\}\}$ is **not** countable

Last time: Uncomputable functions

We have seen that:

- The set of all (Java) programs is countable
- The set of all functions $f : \mathbb{N} \to \{0, \dots, 9\}$ is not countable

So: There must be some function $f : \mathbb{N} \to \{0, ..., 9\}$ that is not computable by any program!

Uncomputable functions

Interesting... maybe.

Can we come up with an explicit function that is uncomputable?

A "Simple" Program

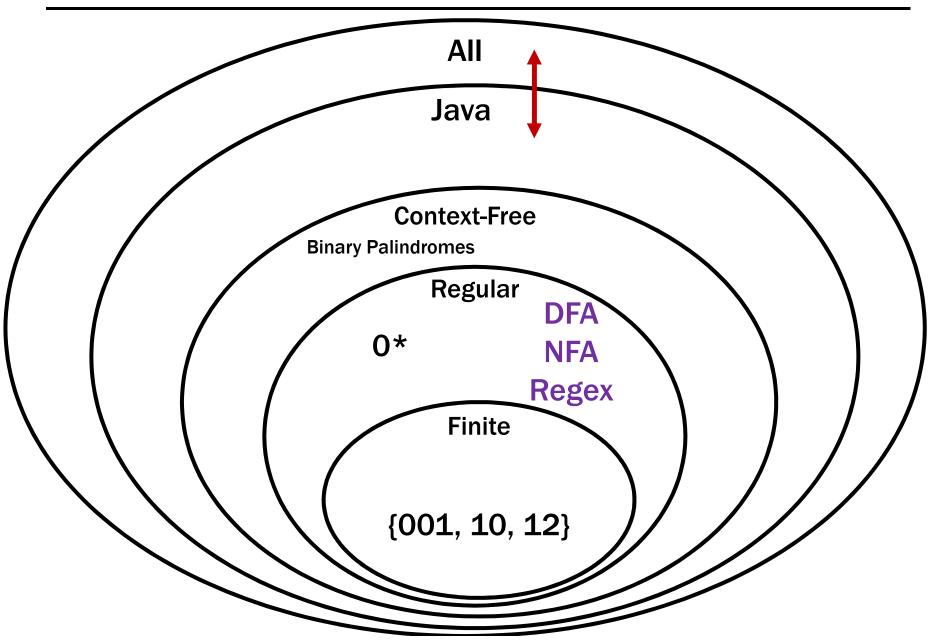

<pre>public static void collatz(n) {</pre>	11
if (n == 1) {	34
return 1;	17
}	52
if $(n \% 2 == 0) \{$	26
return collatz(n/2) }	13
J else {	40
return collatz(3*n + 1)	20
}	10
}	5
	16
What does this program do?	8
on n=11?	4
on n=1000000000000000000001?	2
	1

A "Simple" Program

```
public static void collatz(n) {
   if (n == 1) {
       return 1;
   }
   if (n % 2 == 0) {
       return collatz(n/2)
   }
   else {
       return collatz(3*n + 1)
   }
}
                                Nobody knows whether or not
                                this program halts on all inputs!
What does this program do?
```

- ... on n=11?

Recall our language picture

We're going to be talking about Java code.

CODE(P) will mean "the code of the program P"

So, consider the following function:
 public String P(<u>String</u> x) {
 return new String(Arrays.sort(x.toCharArray());
 }

What is **P(CODE(P))**?

"((((())))..;AACPSSaaabceeggghiiiilnnnnnooprrrrrrrrssstttttuuwxxyy{}"

CODE(P) means "the code of the program **P**"

The Halting Problem

Given: - CODE(**P**) for any program **P** - input **x**

Output: true if P halts on input x false if P does not halt on input x

Undecidability of the Halting Problem

CODE(P) means "the code of the program **P**"

The Halting Problem

Given: - CODE(**P**) for any program **P** - input **x**

Output: true if P halts on input x false if P does not halt on input x

Theorem [Turing]: There is no program that solves the Halting Problem

(rode (p), x)

Suppose that H is a Java program that solves the Halting problem.

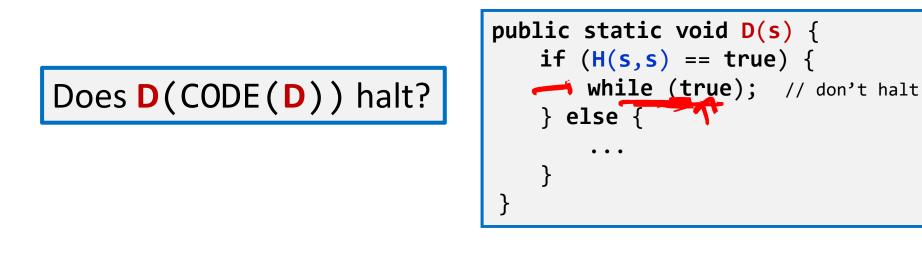

Suppose that H is a Java program that solves the Halting problem.

Then we can write this program:

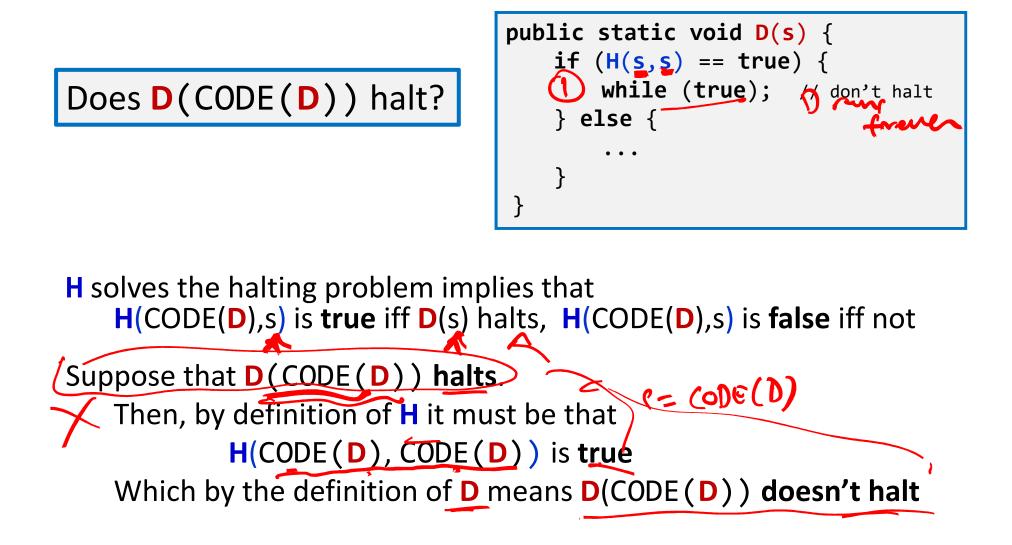

```
public static void D(String s) {
    if (H(s,s) == true) {
        while (true); // don't halt
    } else {
        return; // halt
    }
}
public static bool H(String s, String x) { ... }
```

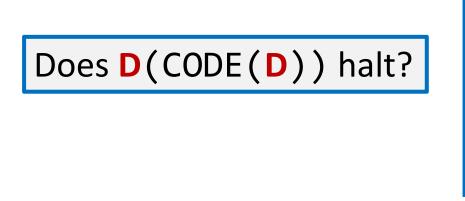

Does D(CODE(D)) halt?

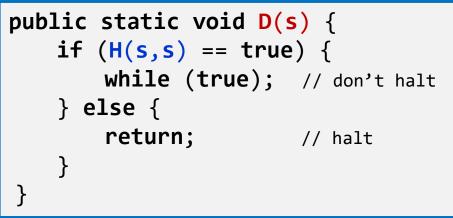

H solves the halting problem implies that H(CODE(D),s) is **true** iff D(s) halts, H(CODE(D),s) is **false** iff not

H solves the halting problem implies that H(CODE(D),s) is **true** iff D(s) halts, H(CODE(D),s) is **false** iff not

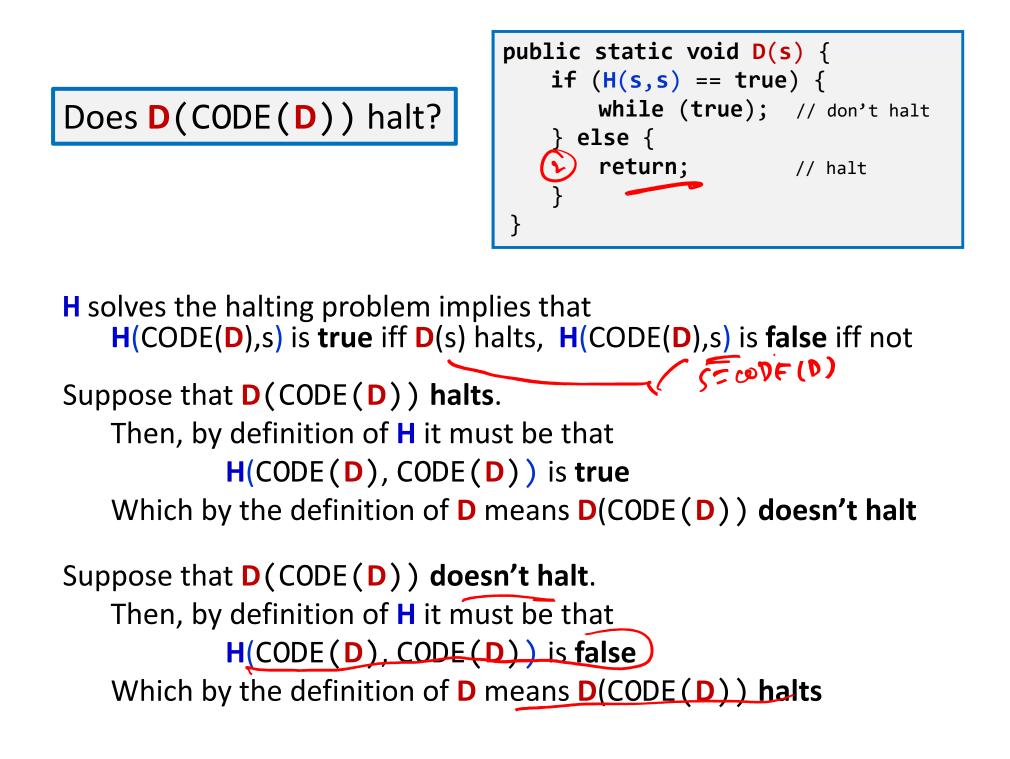

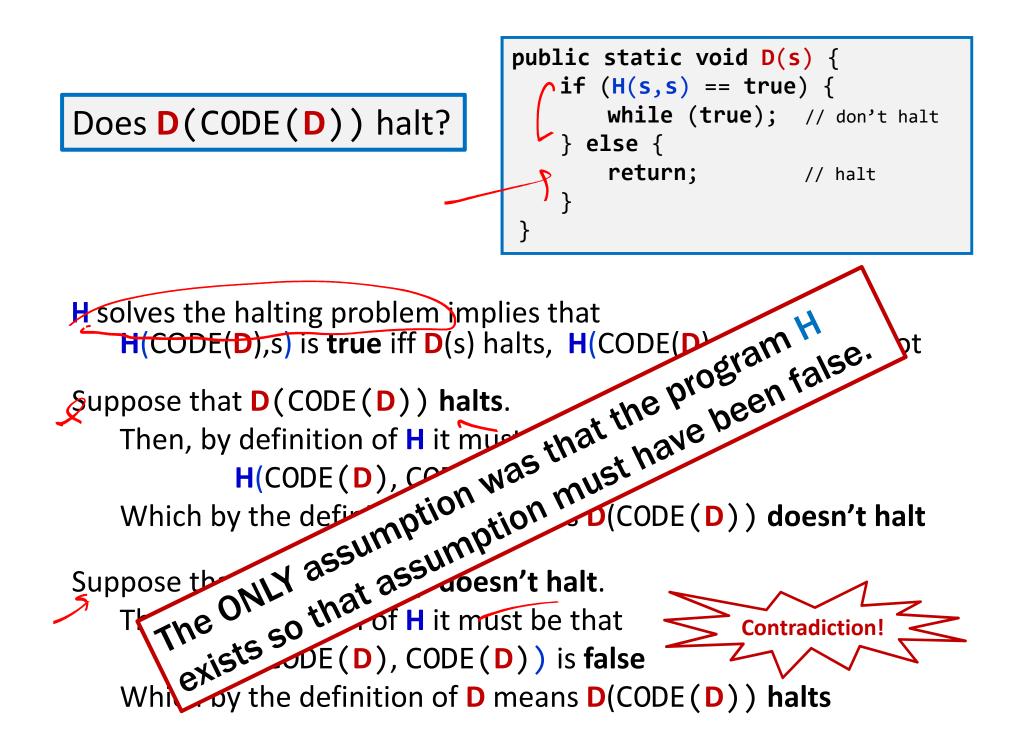

H solves the halting problem implies that H(CODE(D),s) is true iff D(s) halts, H(CODE(D),s) is false iff not

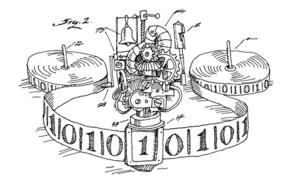

Suppose that D(CODE(D)) halts.
Then, by definition of H it must be that
H(CODE(D), CODE(D)) is true
Which by the definition of D means D(CODE(D)) doesn't halt

- We proved that there is no computer program that can solve the Halting Problem.
 - There was nothing special about Java*

[Church-Turing thesis]

 This tells us that there is no compiler that can check our programs and guarantee to find any infinite loops they might have.

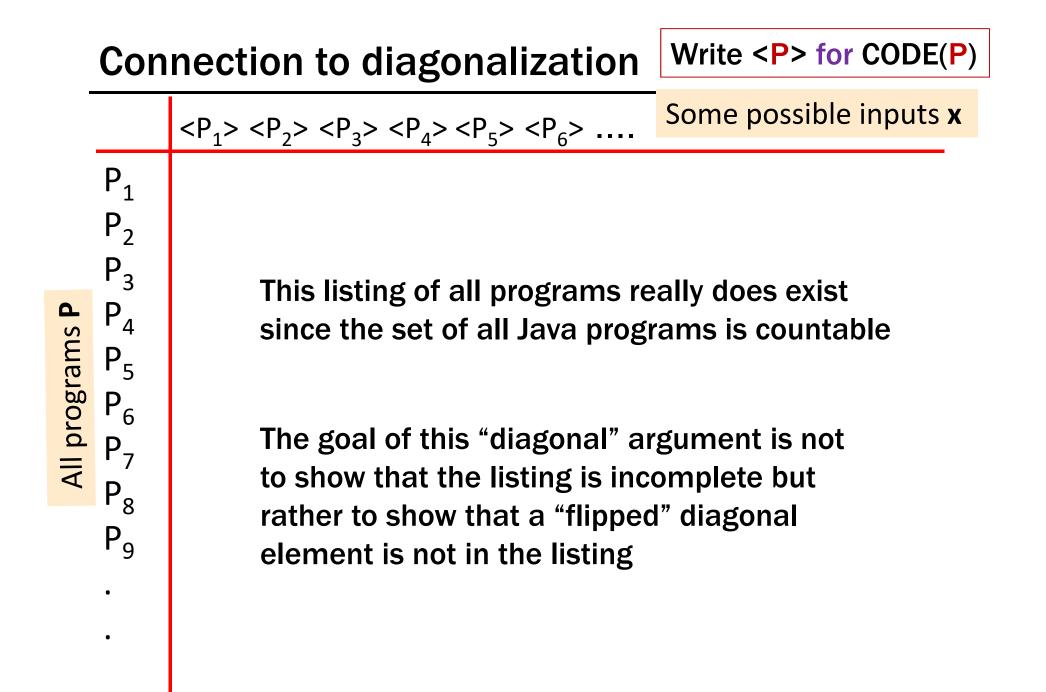

Terminology

- With state machines, we say that a machine "recognizes" the language L iff
 - it accepts $x \in \Sigma^*$ if $x \in L$
 - it rejects $x \in \Sigma^*$ if $x \notin L$
- With Java programs / general computation, we say that the computer "decides" the language L iff
 - it halts with output 1 on input $x \in \Sigma^*$ if $x \in L$
 - it halts with output 0 on input $x \in \Sigma^*$ if $x \notin L$ (difference is the possibility that machine doesn't halt)
- If no machine decides L, then L is "undecidable"

Where did the idea for creating **D** come from?

	Con	nec	tion	to d	iag	Write < P > for CODE(P)								
-		<p<sub>1> <p<sub>2> <p<sub>3> <p<sub>4> <p<sub>5> <p<sub>6></p<sub></p<sub></p<sub></p<sub></p<sub></p<sub>								Some possible inputs x				
	P ₁	0	1	1	0	1	1	1	0	0	0	1		
	P_2	1	1	0	1	0	1	1	0	1	1	1		
	P_3	1	0	1	0	0	0	0	0	0	0	1		
All programs P	P_4	0	1	1	0	1	0	1	1	0	1	0		
	P ₅	0	1	1	1	1	1	1	0	0	0	1		
	P_6	1	1	0	0	0	1	1	0	1	1	1		
	P ₇	1	0	1	1	0	0	0	0	0	0	1		
	P ₈	0	1	1	1	1	0	1	1	0	1	0		
	P ₉				•		•	• •						
	•	•	• •		•	• •	•	• •		•				
	•	(P,x) entry is 1 if program P halts on input x												

and **0** if it runs forever

I

Where did the idea for creating **D** come from?

Therefore, for any program P, **D** differs from P on input code(P)
