

Quantifier Negation and Direct Proof

CSE 311: Autumn 25
Lecture 7

Some slides adapted from Anjali Agarwal

Nested Quantifiers

Nested Quantifiers

Translate these sentences using only quantifiers and the predicate $\text{AreFriends}(x, y)$

Everyone is friends with someone.

Someone is friends with everyone.

Nested Quantifiers

Translate these sentences using only quantifiers and the predicate $\text{AreFriends}(x, y)$

Everyone is friends with someone.

$\forall x(\exists y \text{AreFriends}(x, y))$

$\forall x \exists y \text{AreFriends}(x, y)$

Someone is friends with everyone.

$\exists x(\forall y \text{AreFriends}(x, y))$

$\exists x \forall y \text{AreFriends}(x, y)$

Nested Quantifiers

$$\forall x \exists y P(x, y)$$

"For every x there exists a y such that $P(x, y)$ is true."

y might change depending on the x (people have different friends!).

$$\exists x \forall y P(x, y)$$

"There is an x such that for all y , $P(x, y)$ is true."

There's a special, magical x value so that $P(x, y)$ is true regardless of y .

Nested Quantifiers

Let our domain of discourse be $\{A, B, C, D, E\}$

And our proposition $P(x, y)$ be given by the table.

What should we look for in the table?

$\exists x \forall y P(x, y)$

$\forall x \exists y P(x, y)$

$P(B, C)$

$P(x, y)$	A	B	C	D	E
A	T	T	T	T	T
B	T	F	F	T	F
C	F	T	F	F	F
D	F	F	F	F	T
E	F	F	F	T	F

Nested Quantifiers

Let our domain of discourse be $\{A, B, C, D, E\}$

And our proposition $P(x, y)$ be given by the table.

What should we look for in the table?

$$\exists x \forall y P(x, y) \rightarrow \text{T}$$

A row, where every entry is T

$$\forall x \exists y P(x, y) \rightarrow \text{T}$$

In every row there must be a T

$P(x, y)$	A	B	C	D	E
A	T	T	T	T	T
B	T	F	F	T	F
C	F	T	F	F	F
D	F	F	F	F	T
E	F	F	F	T	F

Keep everything in order

Keep the quantifiers in the same order in English as they are in the logical notation.

“There is someone out there for everyone” is a $\forall x \exists y$ statement in “everyday” English.

It would **never** be phrased that way in “mathematical English” We’ll only ever write “for every person, there is someone out there for them.”

Try it yourselves

$\forall x \exists y (\text{Cat}(x) \rightarrow \text{Loves}(x, y) \wedge \text{Human}(y))$

$\exists x \forall y (\text{Cat}(x) \rightarrow \text{Loves}(x, y) \wedge \text{Human}(y))$

Every x cat loves some y human.

There is a cat that loves every human.

Let your domain of discourse be mammals.

Use the predicates $\text{Cat}(x)$, ~~$\text{Dog}(x)$~~ , and $\text{Loves}(x, y)$ to mean x loves y .

~~$\text{Human}(x)$~~

Try it yourselves

Every cat loves some human.

There is a cat that loves every human.

$$\forall x (\text{Cat}(x) \rightarrow \exists y [\text{Human}(y) \wedge \text{Loves}(x, y)])$$

$$\forall x \exists y (\text{Cat}(x) \rightarrow [\text{Human}(y) \wedge \text{Loves}(x, y)])$$

Loves(x,y) ∧ Human(y)

$$\exists x (\text{Cat}(x) \wedge \forall y [\text{Human}(y) \rightarrow \text{Loves}(x, y)])$$

$$\exists x \forall y (\text{Cat}(x) \wedge [\text{Human}(y) \rightarrow \text{Loves}(x, y)])$$

Negation

How do we negate nested quantifiers?

The old rule still applies.

To negate an expression with a quantifier

1. Switch the quantifier (\forall becomes \exists , \exists becomes \forall)
2. Negate the expression inside

$$\neg(\forall x \exists y \forall z [P(x, y) \wedge Q(y, z)])$$

$$\exists x (\neg(\exists y \forall z [P(x, y) \wedge Q(y, z)]))$$

$$\exists x \forall y (\neg(\forall z [P(x, y) \wedge Q(y, z)]))$$

$$\exists x \forall y \exists z (\neg[P(x, y) \wedge Q(y, z)])$$

$$\exists x \forall y \exists z [\neg P(x, y) \vee \neg Q(y, z)]$$

More Translation

For each of the following, translate it, then say whether the statement is true. Let your domain of discourse be integers.

For every integer, there is a greater integer.

$\forall x \exists y (\text{Greater}(y, x))$ (This statement is true: y can be $x + 1$ [y depends on x])

There is an integer x , such that for all integers y , xy is equal to 1.

$\exists x \forall y (\text{Equal}(xy, 1))$ (This statement is false: no single value of x can play that role for every y .)

$\forall y \exists x (\text{Equal}(x + y, 1))$

For every integer, y , there is an integer x such that $x + y = 1$
(This statement is true, y can depend on x)

Theorems and Proofs

Theorems and Proofs

Theorem: A statement that has been proven to be true.

Proof: A valid argument that establishes a statement to be true.

You'll also see

↳ "claim" (the statement we're about to prove)

↳ "lemma" (small theorem, used to prove a bigger theorem)

↳ "corollary" (small theorem, proven using a bigger theorem)

Theorems and Proofs

Examples of theorems include...

- Given a right triangle with side lengths a, b and hypotenuse c ,
 $a^2 + b^2 = c^2$
- There are infinitely many prime numbers. ←
- There exists a problem that cannot be solved by a program. ↩

Integer

We need a basic starting point to be able to prove things.

Objects to work with.

An integer: is any real number with no fractional part.

Some definitions to analyze

Even

$\text{Even}(x) :=$ An integer, x , is even if and only if there is an integer k such that $x = 2k$.

Odd

$\text{Odd}(x) :=$ An integer, x , is odd if and only if there is an integer k such that $x = 2k + 1$.

A word on definitions

Definitions are fundamental. Our goal is to communicate precisely.

When you come across an edge case, a definition is the way to solve it.

Is -4 even? Well $\exists k(-4 = 2k)$ (take $k = -2$), so yes it is!

We go to the definition. Not your gut feeling about what feels right.

How do we know something is true? Usually we verify the definition!

A word on definitions

How do we know something is true? Usually we verify the definition!

In other resources (textbooks, Wikipedia, etc.)

You will see things that look like this:

Definition: An integer, x , is even if $\exists k(x = 2k)$.

Notice it says "if" not "if and only if."

A definition is **always** an if and only if. The word "definition" has the "only if" direction in it.

I really wish people didn't do this. I wish they explicitly said "if and only if" but some people insist that "definition" implies the "only if" direction. Otherwise it's a "sufficient condition" not a "definition"

Proof Strategy: Direct Proof

Direct Proof

Direct proof is one strategy for proving statements of the form

$$\forall x [P(x) \rightarrow Q(x)]$$

Our First Direct Proof

Prove: "For all integers x , if x is even, then x^2 is even."

What's the claim in logic?

How would we prove this claim?

We'll see how to prove it formally in a minute; for now, just try to convince each other this statement is true.

Our First Direct Proof

Definitions

$$\text{Even}(x) := \exists k(x = 2k)$$

Prove: "For all integers x , if x is even, then x^2 is even." $\forall x(\text{Even}(x) \rightarrow \text{Even}(x^2))$

Arbitrary

An “arbitrary” variable is one that is ~~part of the domain~~ of discourse (or some sub-domain you pick). You know **nothing** else about.

EVERY element of the domain could be plugged into that arbitrary variable. And everything else you say in the proof will follow.

[An arbitrary variable is exactly what you need to convince us of a \forall .

If you want to prove a for-all you must explicitly tell us the variable is arbitrary when it is introduced.

Your reader doesn't know what you're doing otherwise.

Our First Direct Proof

Definitions

$$\text{Even}(x) := \exists k(x = 2k)$$

Prove: "For all integers x , if x is even, then x^2 is even." $\forall x(\text{Even}(x) \rightarrow \text{Even}(x^2))$

Proof: Let x be an arbitrary integer. Suppose that x is even.

Now What?

Definitions

$$\text{Even}(x) := \exists k(x = 2k)$$

Well...what does it mean to be even?

$x = 2k$ for some integer k .

Where do we need to end up?

$\text{Even}(x^2)$

Our First Direct Proof

Definitions

$$\text{Even}(x) := \exists k(x = 2k)$$

Prove: "For all integers x , if x is even, then x^2 is even." $\forall x(\text{Even}(x) \rightarrow \text{Even}(x^2))$

Proof: Let x be an arbitrary integer. Suppose that x is even.

So x^2 is even.

Our First Direct Proof

Definitions

$$\text{Even}(x) := \exists k(x = 2k)$$

Prove: "For all integers x , if x is even, then x^2 is even." $\forall x(\text{Even}(x) \rightarrow \text{Even}(x^2))$

Proof: Let x be an arbitrary integer. Suppose that x is even.

By definition of even, $x = 2k$ for some integer k .

So x^2 is even.

Our First Direct Proof

Definitions

$$\text{Even}(x) := \exists k(x = 2k)$$

Prove: "For all integers x , if x is even, then x^2 is even." $\forall x(\text{Even}(x) \rightarrow \text{Even}(x^2))$

Proof: Let x be an arbitrary integer. Suppose that x is even.

By definition of even, $x = 2k$ for some integer k .

Squaring both sides, we see that:

$$x^2 = (2k)^2 = 4k^2 = 2 \cdot 2k^2$$

Because k is an integer, $2k^2$ is also an integer.

So x^2 is two times an integer.

Which is exactly the definition of even, so x^2 is even.

Since x was an arbitrary integer, we conclude that for all integers x , if x is even then x^2 is also even.

Direct Proof Template

Declare an arbitrary variable for each \forall .

Assume the left side of the implication.

Unroll the predicate definitions.

Manipulate towards the goal.

Reroll definitions into the right side of the implication.

Conclude that you have proved the claim.

Prove: $\forall x(\text{Even}(x) \rightarrow \text{Even}(x^2))$

Let x be an arbitrary integer.

Suppose that x is even.

Then by definition of even, there exists some integer k such that $x = 2k$.

Squaring both sides, we see that:

$$x^2 = (2k)^2 = 4k^2 = 2 \cdot 2k^2$$

Because k is an integer, then $2k^2$ is also an integer. So x^2 is two times an integer.

So by definition of even, x^2 is even.

Since x was an arbitrary integer, we can conclude that for all integers x , if x is even then x^2 is even.

Direct Proof Steps

These are the usual steps. We'll see different outlines in the future!!

- Introduction
 - Declare an arbitrary variable for each \forall quantifier
 - Assume the left side of the implication
- Core of the proof
 - Unroll the predicate definitions
 - Manipulate towards the goal (using creativity, algebra, etc.)
 - Reroll definitions into the right side of the implication
- Conclude that you have proved the claim

Inference Proofs

A Brief Return to Training Wheels

For about 1.5 lectures, we're going to study "inference proofs"

The rules for these proofs are

1. Strict enough that computers can check them (there are languages designed to do that!)
2. More general than the simplification rules we've seen so far.
You'll still use the simplification rules!
But you'll find we can prove more things (at least without significant difficulty).
3. More similar to the proofs we spend most of the quarter writing.

A Brief Return to Training Wheels

The claims and proofs are quite abstract!

Why spend time here?

Some computer scientists use the fully formal (computer-checkable) version of the rules.

Our PL group here contains experts in these topics!

We want your takeaways to be

In principle, any proof we write in this class could be made fully formal and checked.

But it can be a lot of work, so we usually think and communicate in English. We're people after all!

Inference Proofs

A new way of thinking of proofs:

Here's one way to get an iron-clad guarantee:

1. Write down all the facts we know.
2. Combine the things we know to derive new facts.
3. Continue until what we want to show is a fact.

Drawing Conclusions

You know "If it is raining, then I have my umbrella"

And "It is raining"

You should conclude.... I have my umbrella!

For whatever you conclude, convert the statement to propositional logic – will your statement hold for any propositions, or is it specific to raining and umbrellas?

I know $(p \rightarrow q)$ and p , I can conclude q

Or said another way: $[(p \rightarrow q) \wedge p] \rightarrow q$

Modus Ponens

The inference from the last slide is always valid. I.e.

$$[(p \rightarrow q) \wedge p] \rightarrow q$$

Has only True rows in its truth table (it's a tautology)

Modus Ponens – a formal proof

$[(p \rightarrow q) \wedge p] \rightarrow q$	$\equiv [(\neg p \vee q) \wedge p] \rightarrow q$	Law of Implication
	$\equiv [p \wedge (\neg p \vee q)] \rightarrow q$	Commutativity
	$\equiv [(p \wedge \neg p) \vee (p \wedge q)] \rightarrow q$	Distributivity
	$\equiv [F \vee (p \wedge q)] \rightarrow q$	Negation
	$\equiv [(p \wedge q) \vee F] \rightarrow q$	Commutativity
	$\equiv [(p \wedge q)] \rightarrow q$	Identity
	$\equiv [\neg(p \wedge q)] \vee q$	Law of Implication
	$\equiv [\neg p \vee \neg q] \vee q$	DeMorgan's Law
	$\equiv \neg p \vee [\neg q \vee q]$	Associativity
	$\equiv \neg p \vee [q \vee \neg q]$	Commutativity
	$\equiv \neg p \vee T$	Negation
	$\equiv T$	Domination

Modus Ponens

The inference from the last slide is always valid. I.e.

$$[(p \rightarrow q) \wedge p] \rightarrow q \equiv \text{T}$$

We use that inference A LOT

So often people gave it a name ("Modus Ponens")

So often...we don't have time to repeat that 12 line proof EVERY TIME.

Let's make this another law we can apply in a single step.

Just like refactoring a method in code.

Notation – Laws of Inference

We're using the " \rightarrow " symbol A LOT.

Too much

Some new notation to make our lives easier.

If we know **both** A and B

\therefore We can conclude any (or all) of C, D

A, B

$\therefore C, D$

" \therefore " means "therefore" – I knew A, B therefore I can conclude C, D .

$$\frac{p \rightarrow q, p}{\therefore q}$$

Modus Ponens, i.e. $[(p \rightarrow q) \wedge p] \rightarrow q$,
in our new notation.
