THE BIG PICTURE SOLUTION
TO THE HALTING PROBLEM

The story so far...

NFAs and regular expressions

Theorem: For any regular expression, there is an NFA that recognizes the same language

Proof idea: Structural induction based on the recursive definition of regular expressions...

Regular Expressions over Σ

- **Basis:**
 - ε is a regular expression
 - a is a regular expression for any $a \in \Sigma$
- **Recursive step:**
 - If **A** and **B** are regular expressions, then so are:
 - $A \cup B$
 - AB
 - A^*

Base Case

- **Case ϵ :**

- **Case a :**

Base Case

- **Case ϵ :**

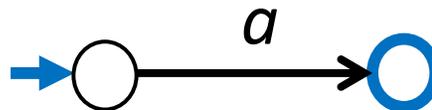

- **Case a :**

Base Case

- **Case ϵ :**

- **Case a :**

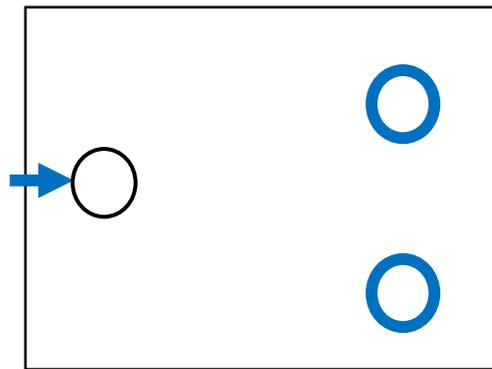

Regular Expressions over Σ

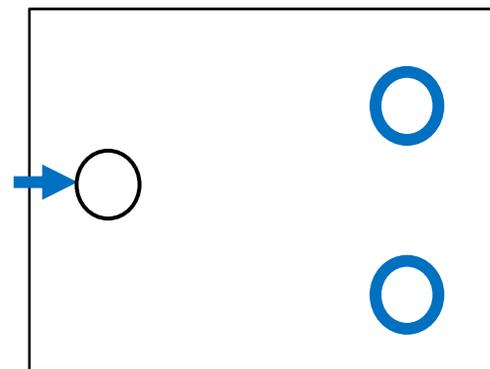

- **Basis:**
 - ε is a regular expression
 - a is a regular expression for any $a \in \Sigma$
- **Recursive step:**
 - If **A** and **B** are regular expressions, then so are:
 - $A \cup B$
 - AB
 - A^*

Inductive Hypothesis

- Suppose that for some regular expressions A and B there exist NFAs N_A and N_B such that N_A recognizes the language given by A and N_B recognizes the language given by B

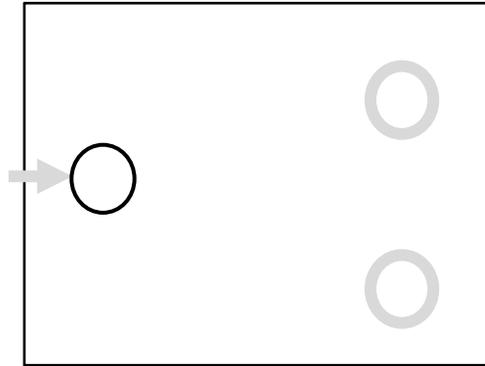

N_A

Inductive Step

Case A*

Build an NFA for $(01 \cup 1)^*0$

Solution

$(01 \cup 1)^*0$

The story so far...

NFAs and DFAs

Every DFA is an NFA

- DFAs have requirements that NFAs don't have

Can NFAs recognize more languages?

NFAs and DFAs

Every DFA is an NFA

- DFAs have requirements that NFAs don't have

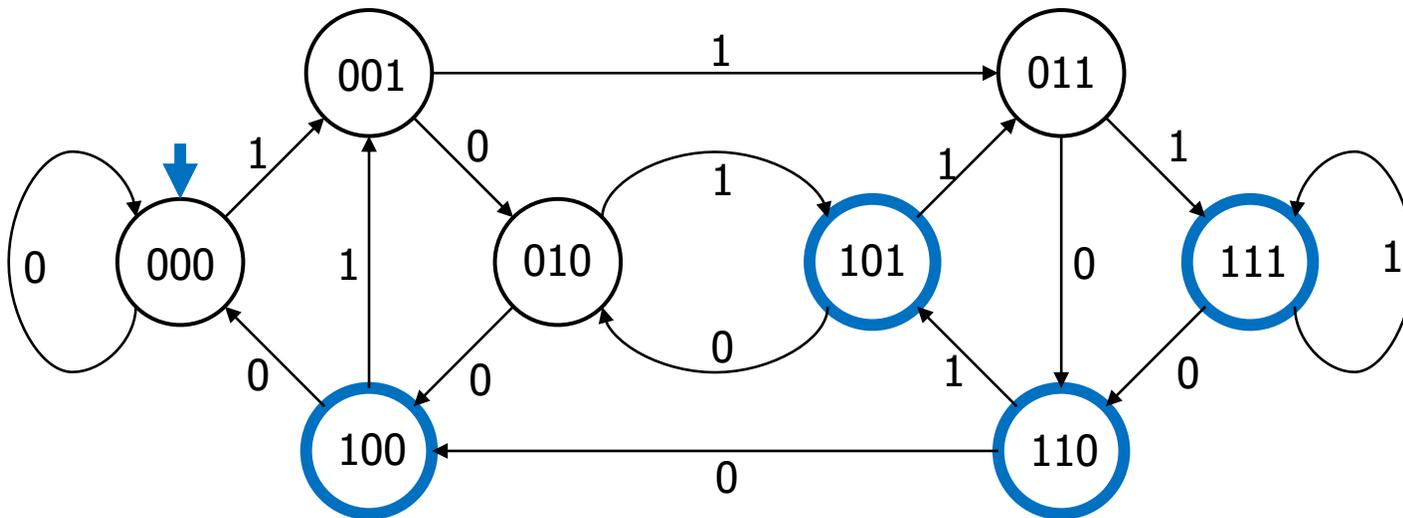

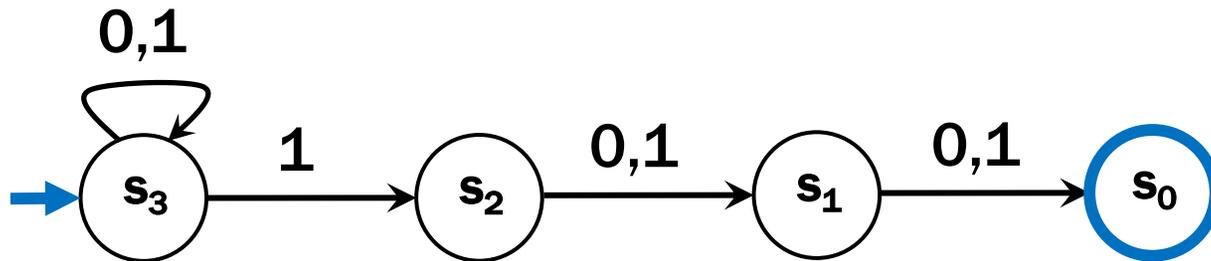

Can NFAs recognize more languages? No!

Theorem: For every NFA there is a DFA that recognizes exactly the same language

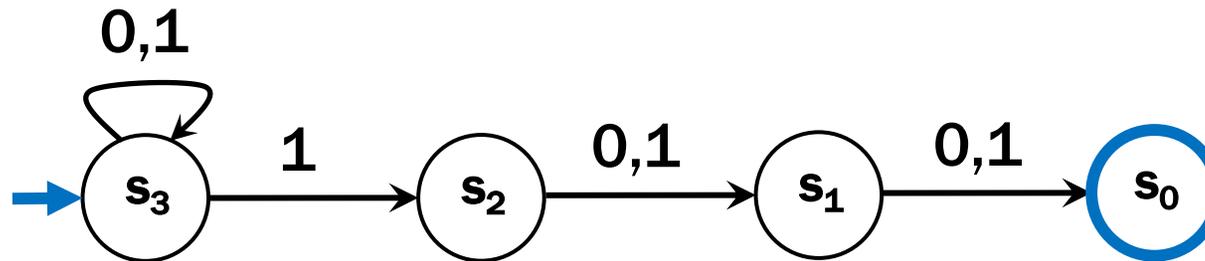

Three ways of thinking about NFAs

- **Perfect guesser:** The NFA has input x and whenever there is a choice of what to do it magically guesses a good one (if one exists)
- **Outside observer:** Is there a path labeled by x from the start state to some accepting state?
- **Parallel exploration:** The NFA computation runs all possible computations on x step-by-step at the same time in parallel

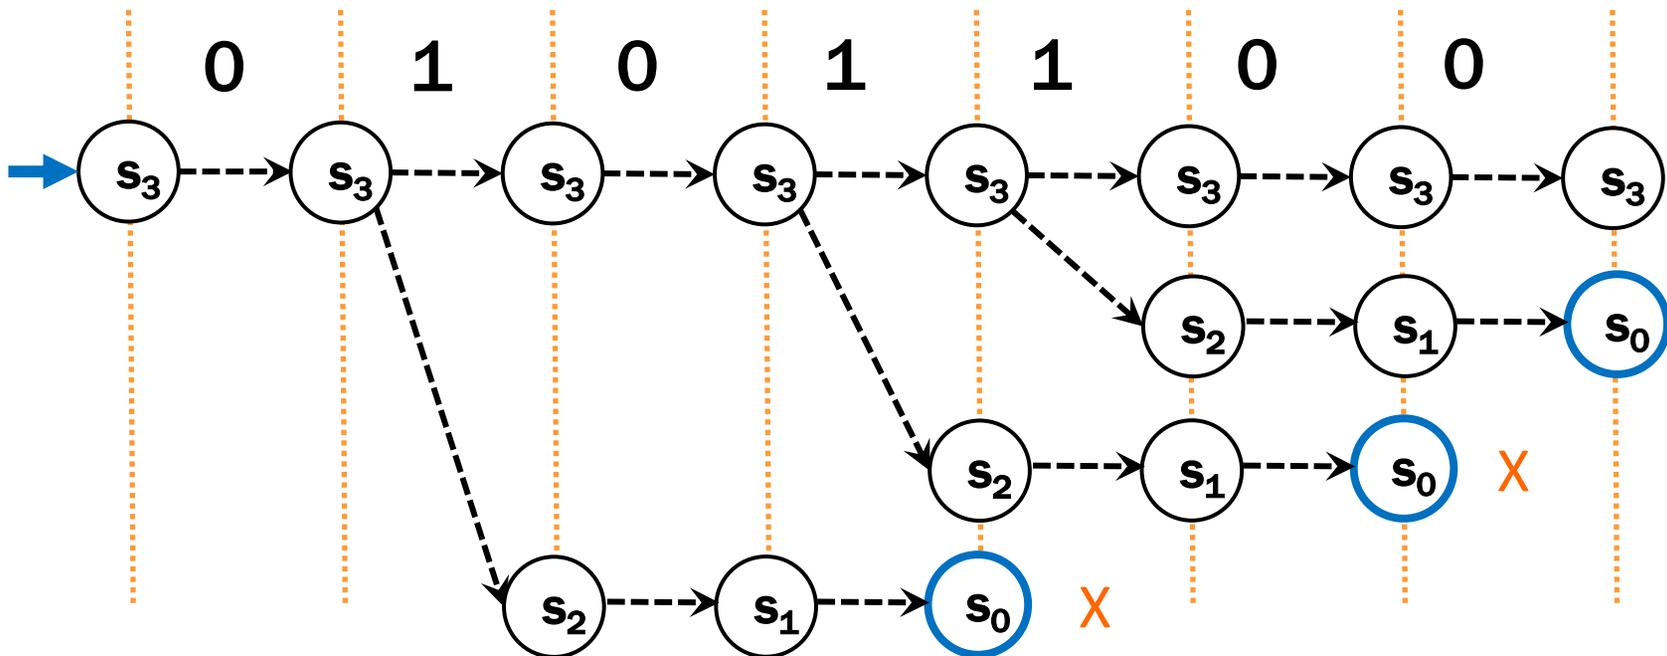

Recall: Compare with the smallest DFA

Parallel Exploration view of an NFA

Input string 0101100

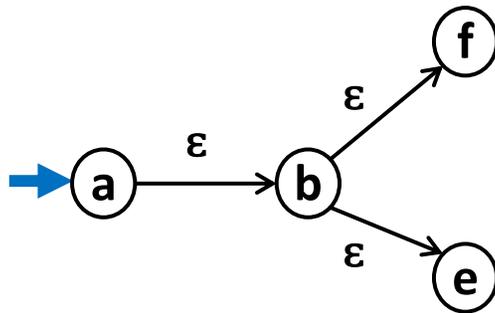

Conversion of NFAs to a DFAs

- **Construction Idea:**
 - The DFA keeps track of **ALL** states reachable in the NFA along a path labeled by the input so far
(Note: not all *paths*; all *last states* on those paths.)
 - There will be one state in the DFA for each *subset* of states of the NFA that can be reached by some string

Conversion of NFAs to a DFAs

New start state for DFA

- The set of all states reachable from the start state of the NFA using only edges labeled ϵ

NFA

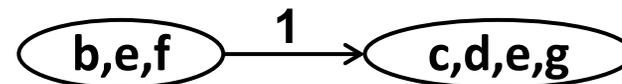

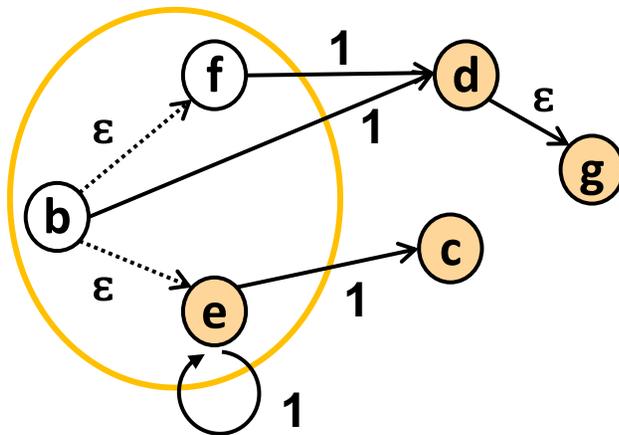

DFA

Conversion of NFAs to a DFAs

For each state of the DFA corresponding to a set S of states of the NFA and each symbol s

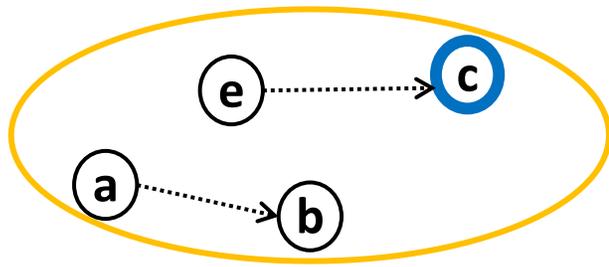

- Add an edge labeled s to state corresponding to T , the set of states of the NFA reached by
 - starting from some state in S , then
 - following one edge labeled by s , and then following some number of edges labeled by ϵ
- T will be \emptyset if no edges from S labeled s exist

Conversion of NFAs to a DFAs

Final states for the DFA

- All states whose set contain some final state of the NFA

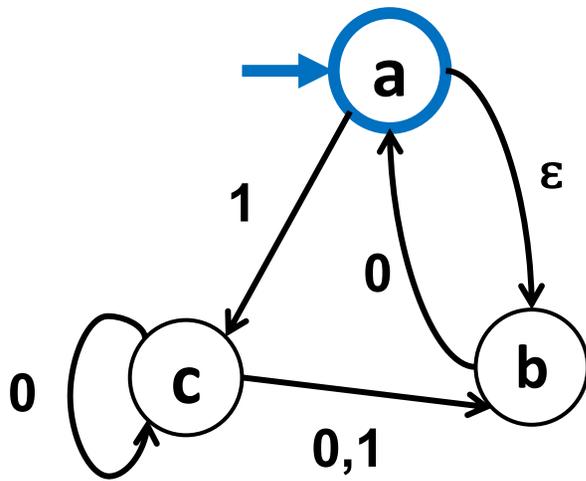

NFA

DFA

Regular expressions, NFAs, & DFAs

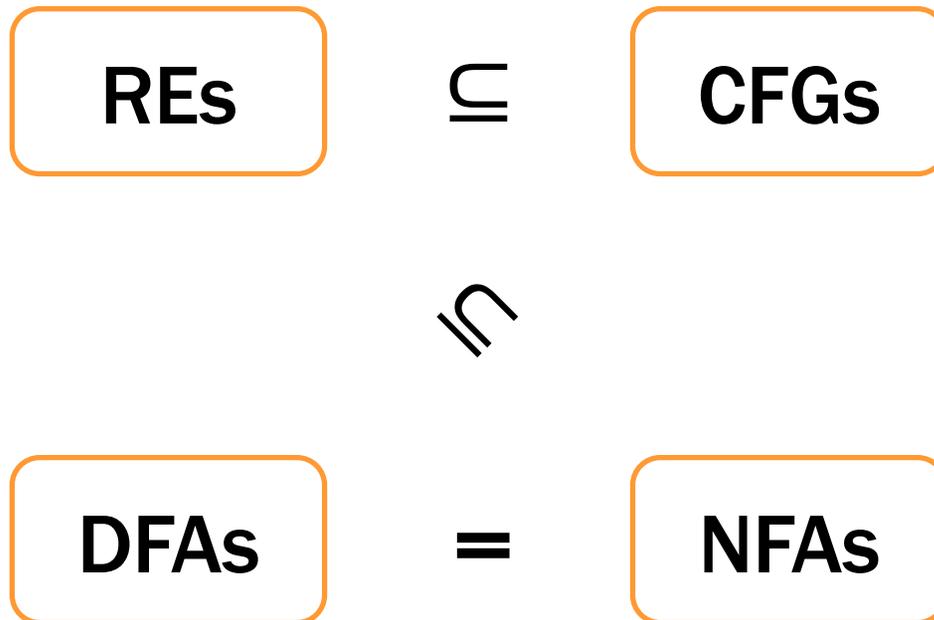

We have shown how to build a DFA for every RE

- Build NFA**
- Convert NFA to DFA using subset construction**
- (Later: minimize resulting DFA)**

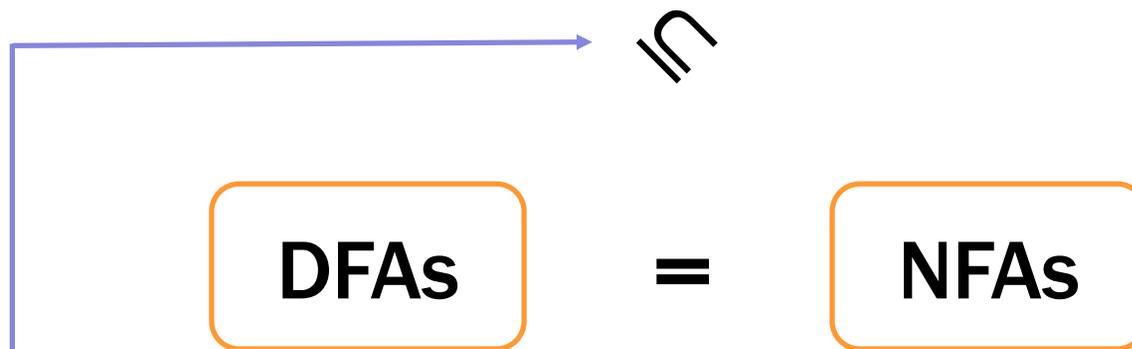

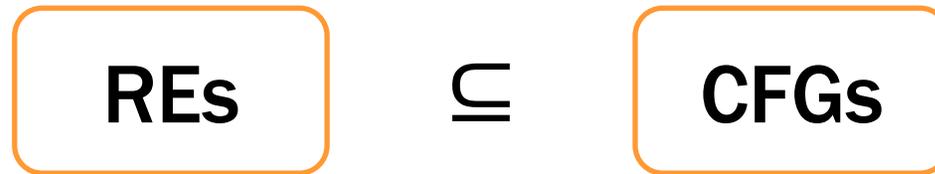

Thus, we could now implement a RegExp library

- most RegExp libraries actually simulate the NFA**
- (even better: one can combine the two approaches:
apply DFA minimization lazily while simulating the NFA)**

The story so far...

The story so far...

Is this \subseteq really "=" or " \subsetneq "?

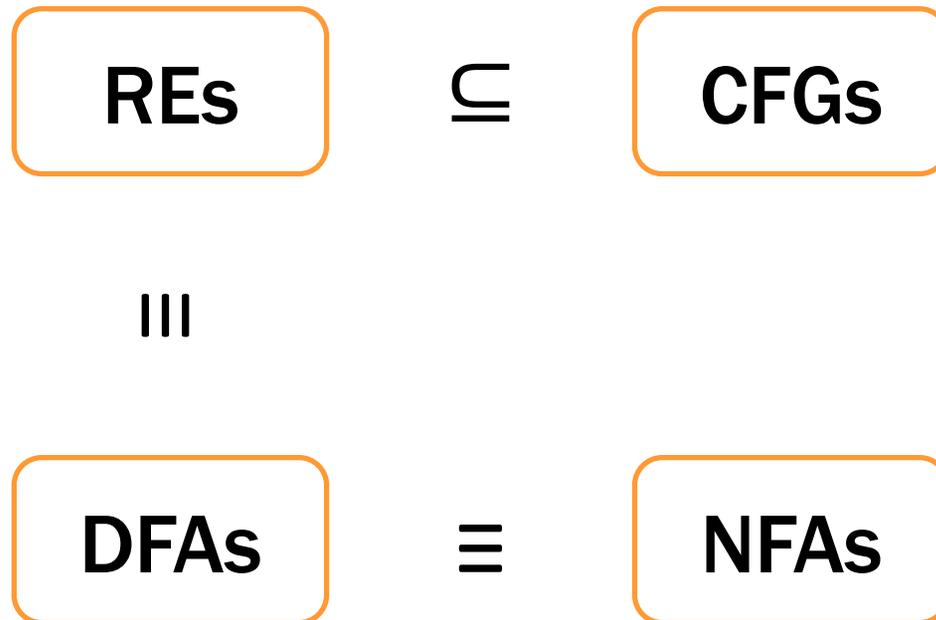

Regular expressions \equiv NFAs \equiv DFAs

Theorem: For any NFA, there is a regular expression that accepts the same language

Corollary: A language is recognized by a DFA (or NFA) if and only if it has a regular expression

You need to know these facts

The story so far...

Languages represented by DFA, NFAs, or regular expressions are called **Regular Languages**

Example Corollary of These Results

Corollary: If A is the language of a regular expression, then \bar{A} is the language of a regular expression*.

(This is the complement with respect to the universe of all strings over the alphabet, i.e., $\bar{A} = \Sigma^* \setminus A$.)

Recall: Algorithms for Regular Languages

We have algorithms for

- RE to NFA
- NFA to DFA
- DFA/NFA to RE (not shown)
- DFA minimization (next...)

State Minimization

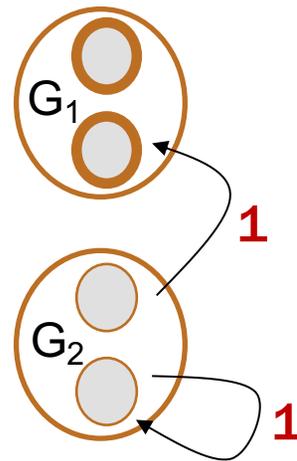

- Many FSMs (DFAs) for the same problem
- Take a given FSM and try to reduce its state set by combining states
 - Algorithm will always produce the unique minimal equivalent machine (up to renaming of states) but we won't prove this

State Minimization Algorithm

- Put states into groups
- Try to find groups that can be collapsed into one state
 - states can keep track of information that isn't necessary to determine whether to accept or reject
- Group states together until we can *prove* that collapsing them can change the accept/reject result

State Minimization Algorithm

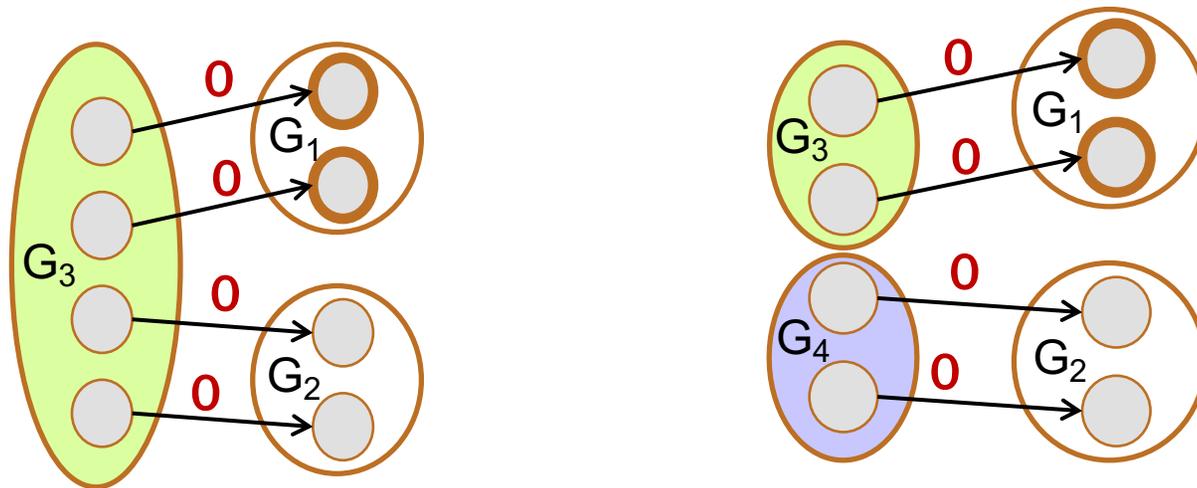

1. Put states into groups based on their outputs (whether they accept or reject)

Must separate G_1 from G_2 because G_1 is **accepting** and G_2 is **rejecting**

State Minimization Algorithm

1. Put states into groups based on their outputs (whether they accept or reject)

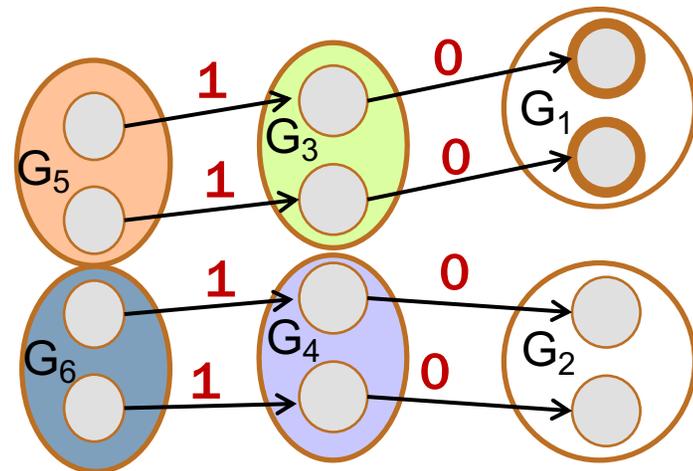

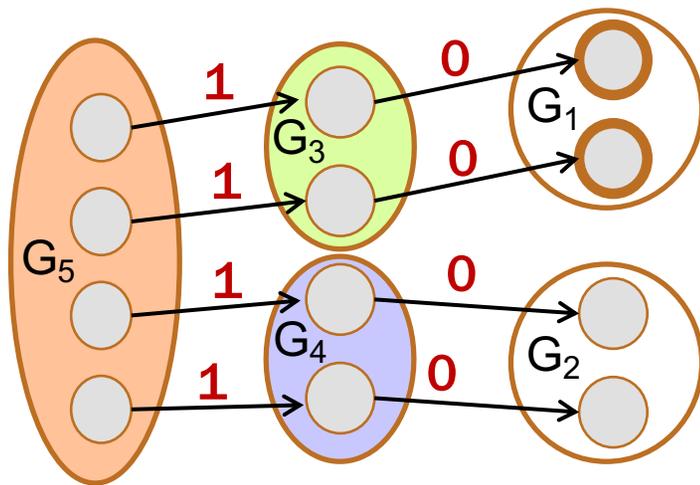

Must separate G_3 from G_4 because on ... 0
 G_3 is **accepting** and G_4 is **rejecting**

State Minimization Algorithm

1. Put states into groups based on their outputs (whether they accept or reject)

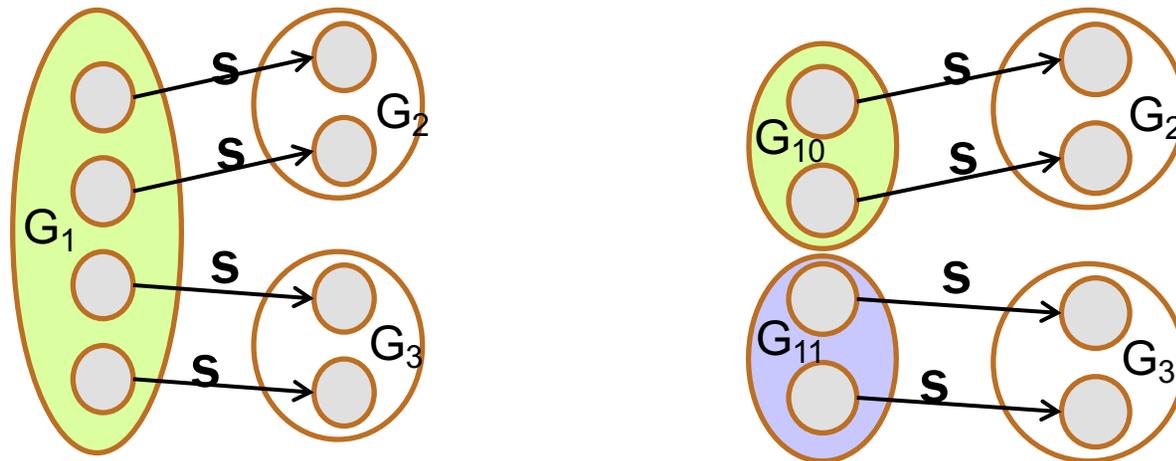

Need to know G_5 vs G_6 if next two characters are "10"

Must separate G_5 from G_6 because on ...**10**
 G_5 is **accepting** and G_6 is **rejecting**

State Minimization Algorithm

1. Put states into groups based on their outputs (whether they accept or reject)
2. Repeat the following until no change happens
 - a. If there is a letter **s** so that not all states in a group **G** agree on which group **s** leads to, split **G** into smaller groups based on which group the states go to on **s**

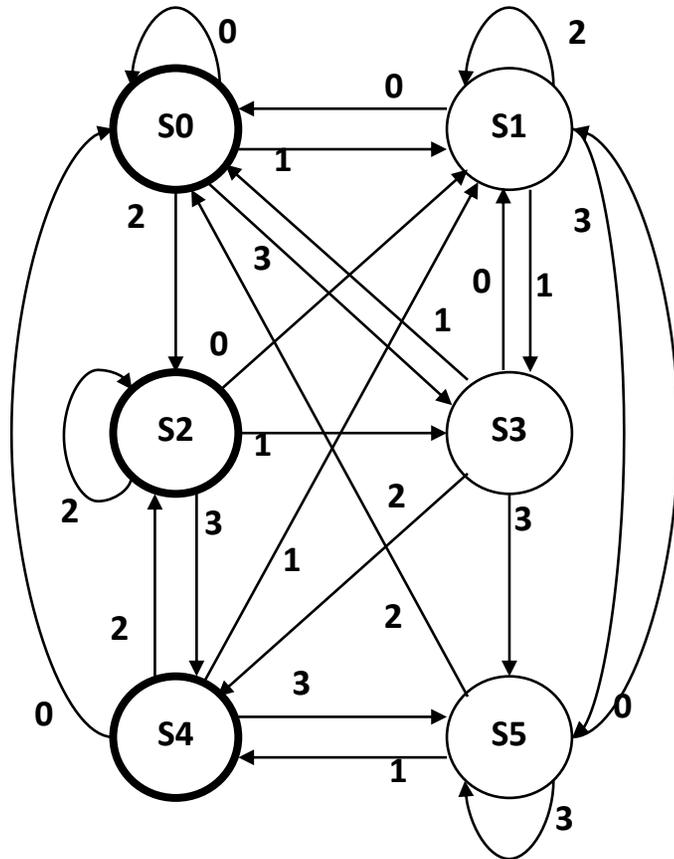

3. Finally, convert groups to states

State Minimization Algorithm

- Put states into groups
- Try to find groups that can be collapsed into one state
 - states can keep track of information that isn't necessary to determine whether to accept or reject
- Group states together until we can *prove* that collapsing them can change the accept/reject result
 - find a specific string **x** such that:
 - starting from state A, following edges according to **x** ends in **accept**
 - starting from state B, following edges according to **x** ends in **reject**
 - algorithm could be modified to calculate these strings

State Minimization Example

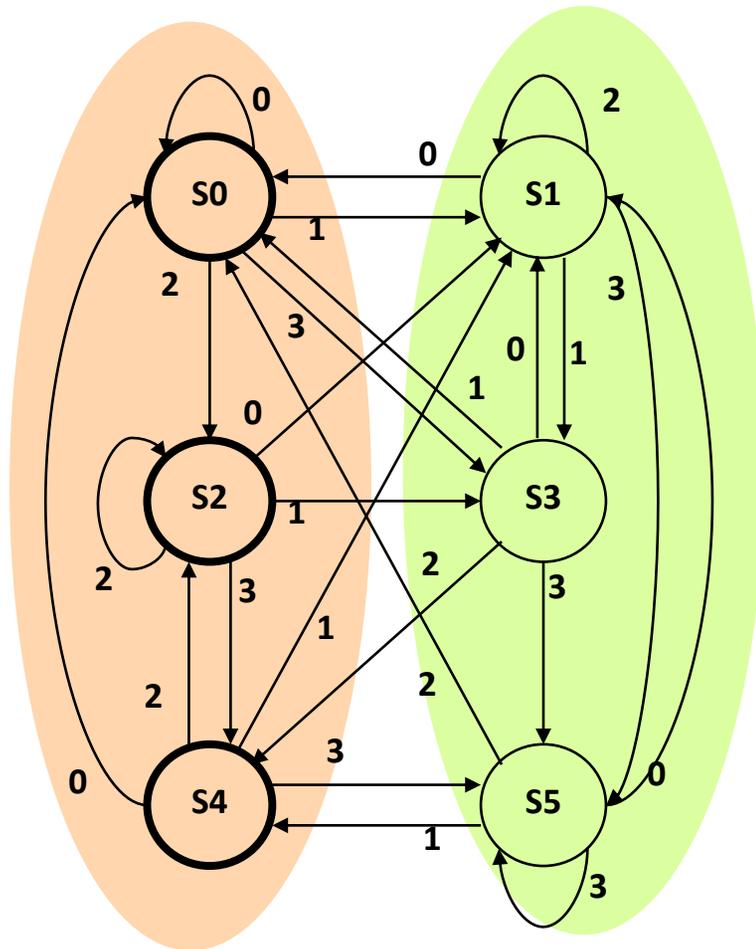

present state	next state				output
	0	1	2	3	
S0	S0	S1	S2	S3	1
S1	S0	S3	S1	S5	0
S2	S1	S3	S2	S4	1

S4	S0	S1	S2	S5	1
S5	S1	S4	S0	S5	0

state transition table

Put states into groups based on their outputs (or whether they accept or reject)

State Minimization Example

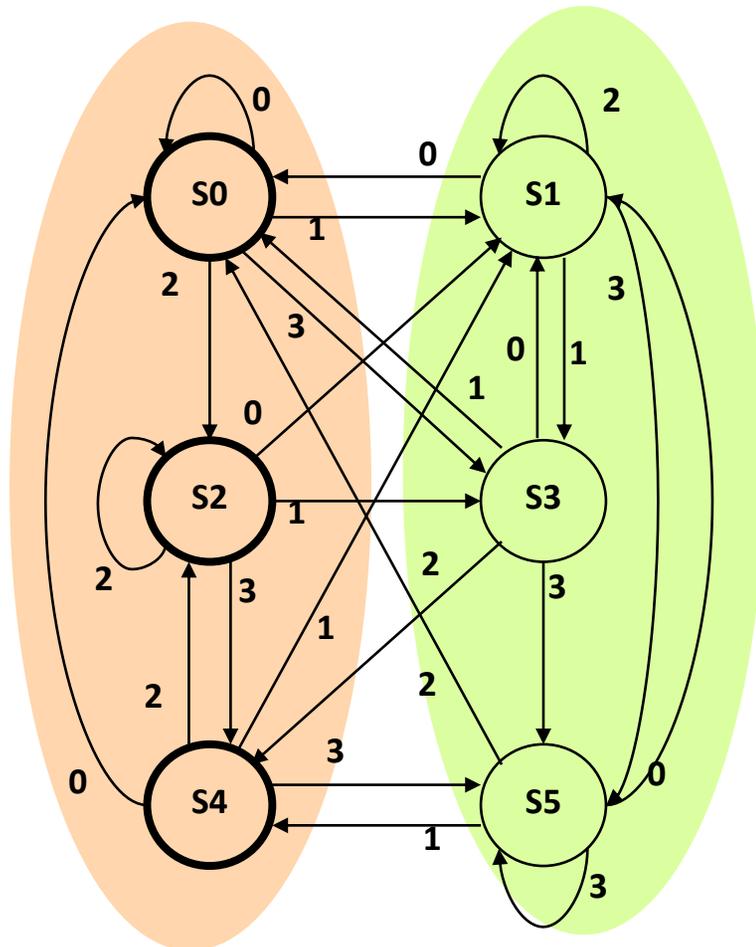

present state	next state				output
	0	1	2	3	
S0	S0	S1	S2	S3	1
S1	S0	S3	S1	S5	0
S2	S1	S3	S2	S4	1
S3	S1	S0	S4	S5	0
S4	S0	S1	S2	S5	1
S5	S1	S4	S0	S5	0

state transition table

Put states into groups based on their outputs (or whether they accept or reject)

State Minimization Example

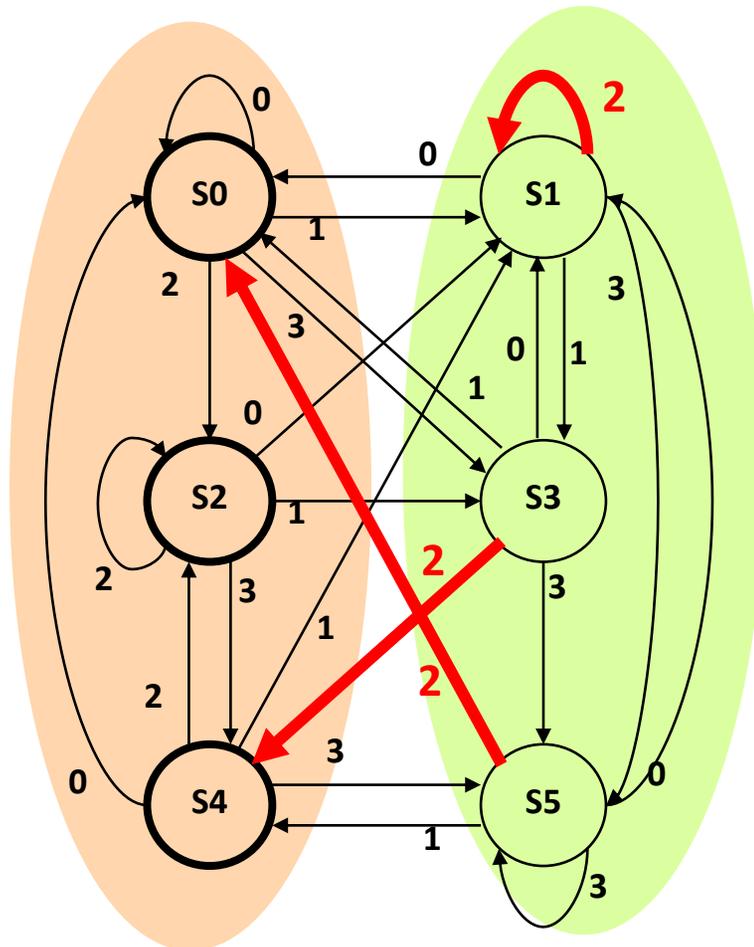

present state	next state				output
	0	1	2	3	
S0	S0	S1	S2	S3	1
S1	S0	S3	S1	S5	0
S2	S1	S3	S2	S4	1
S3	S1	S0	S4	S5	0
S4	S0	S1	S2	S5	1
S5	S1	S4	S0	S5	0

state transition table

Put states into groups based on their outputs (or whether they accept or reject)

If there is a symbol **s** so that not all states in a group **G** agree on which group **s** leads to, split **G** based on which group the states go to on **s**

State Minimization Example

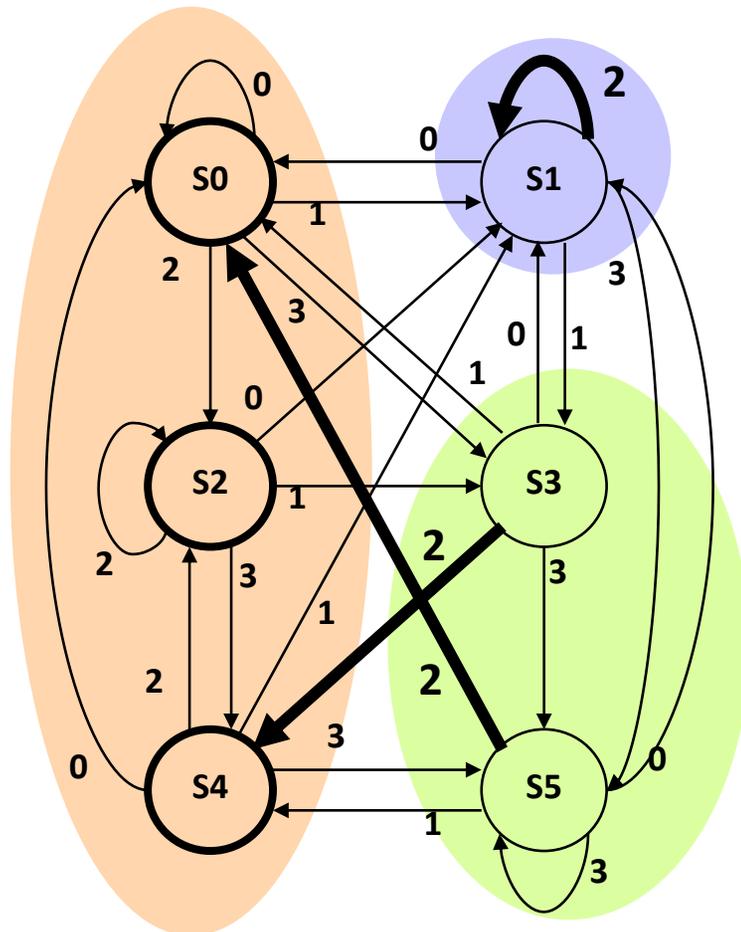

present state	next state				output
	0	1	2	3	
S0	S0	S1	S2	S3	1
S1	S0	S3	S1	S5	0
S2	S1	S3	S2	S4	1
S3	S1	S0	S4	S5	0
S4	S0	S1	S2	S5	1
S5	S1	S4	S0	S5	0

state transition table

Put states into groups based on their outputs (or whether they accept or reject)

If there is a symbol **s** so that not all states in a group **G** agree on which group **s** leads to, split **G** based on which group the states go to on **s**

State Minimization Example

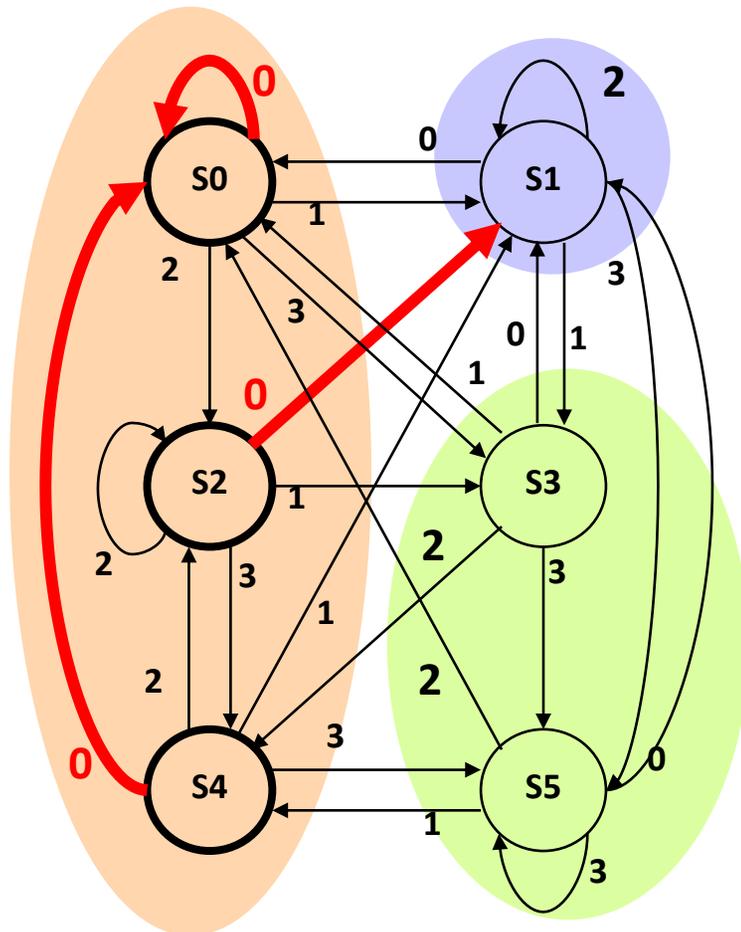

present state	next state				output
	0	1	2	3	
S0	S0	S1	S2	S3	1
S1	S0	S3	S1	S5	0
S2	S1	S3	S2	S4	1
S3	S1	S0	S4	S5	0
S4	S0	S1	S2	S5	1
S5	S1	S4	S0	S5	0

state transition table

Put states into groups based on their outputs (or whether they accept or reject)

If there is a symbol **s** so that not all states in a group **G** agree on which group **s** leads to, split **G** based on which group the states go to on **s**

State Minimization Example

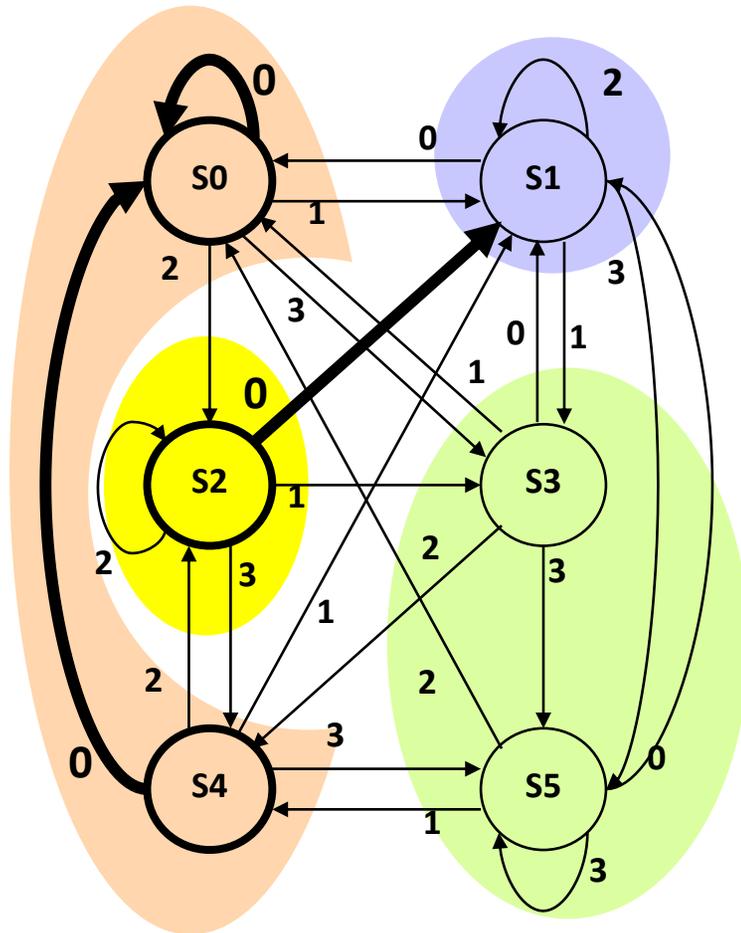

present state	next state				output
	0	1	2	3	
S0	S0	S1	S2	S3	1
S1	S0	S3	S1	S5	0
S2	S1	S3	S2	S4	1
S3	S1	S0	S4	S5	0
S4	S0	S1	S2	S5	1
S5	S1	S4	S0	S5	0

state transition table

Put states into groups based on their outputs (or whether they accept or reject)

If there is a symbol **s** so that not all states in a group **G** agree on which group **s** leads to, split **G** based on which group the states go to on **s**

State Minimization Example

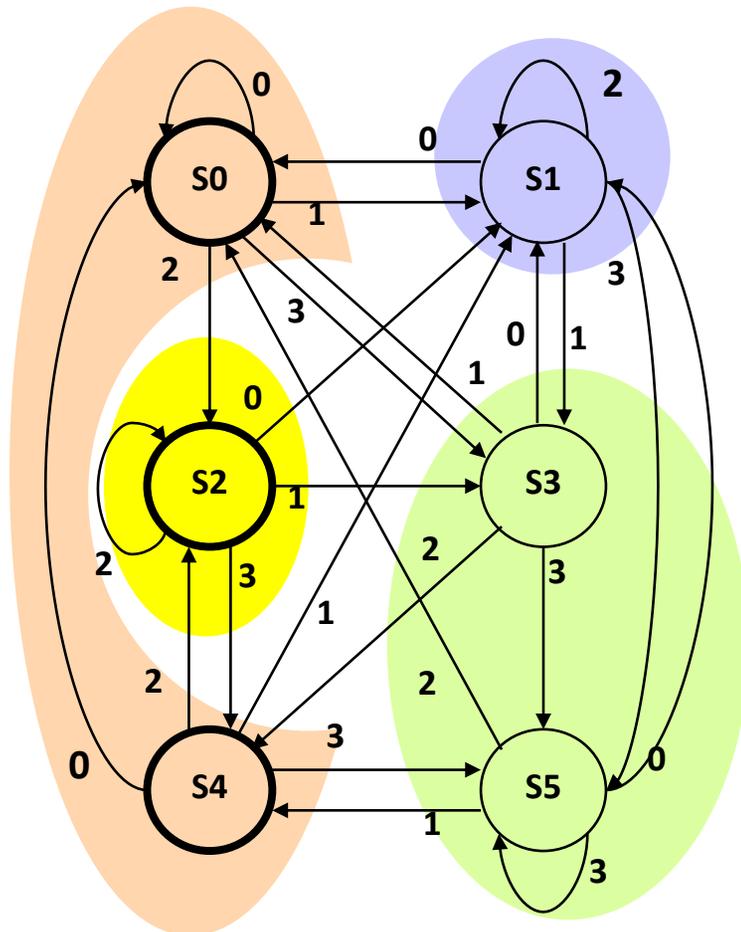

present state	next state				output
	0	1	2	3	
S0	S0	S1	S2	S3	1
S1	S0	S3	S1	S5	0
S2	S1	S3	S2	S4	1
S3	S1	S0	S4	S5	0
S4	S0	S1	S2	S5	1
S5	S1	S4	S0	S5	0

state transition table

Put states into groups based on their outputs (or whether they accept or reject)

If there is a symbol **s** so that not all states in a group **G** agree on which group **s** leads to, split **G** based on which group the states go to on **s**

State Minimization Example

present state	next state				output
	0	1	2	3	
S0	S0	S1	S2	S3	1
S1	S0	S3	S1	S5	0
S2	S1	S3	S2	S4	1
S3	S1	S0	S4	S5	0
S4	S0	S1	S2	S5	1
S5	S1	S4	S0	S5	0

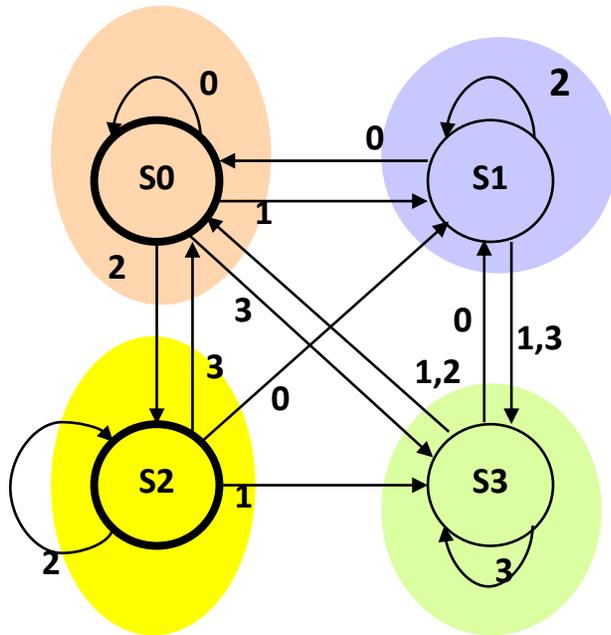

state transition table

Finally convert groups to states:

Can combine states S0-S4 and S3-S5.

In table replace all S4 with S0 and all S5 with S3

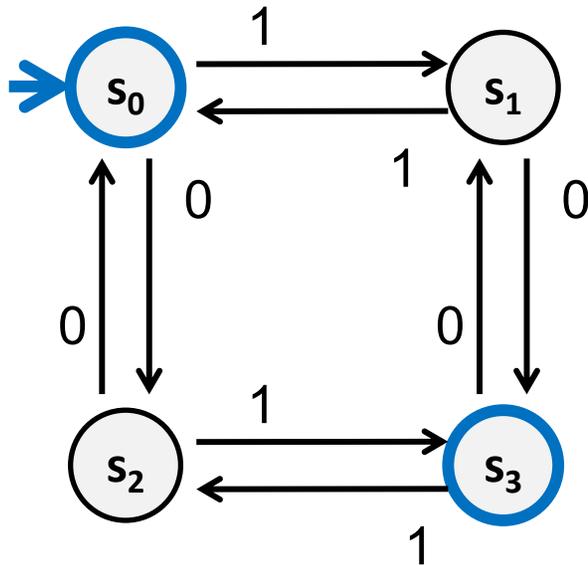

Minimized Machine

present state	next state				output
	0	1	2	3	
S0	S0	S1	S2	S3	1
S1	S0	S3	S1	S3	0
S2	S1	S3	S2	S0	1
S3	S1	S0	S0	S3	0

state transition table

A Simpler Minimization Example

#0s is even

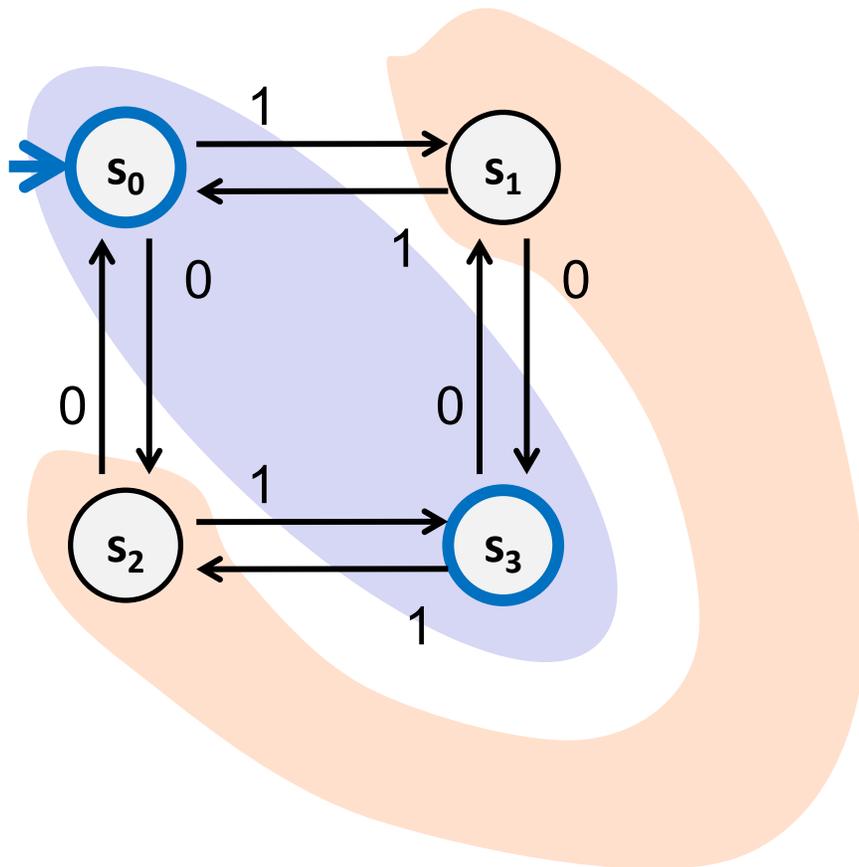

#0s is odd

#1s is even

#1s is odd

The set of all binary strings with # of 1's \equiv # of 0's (mod 2).

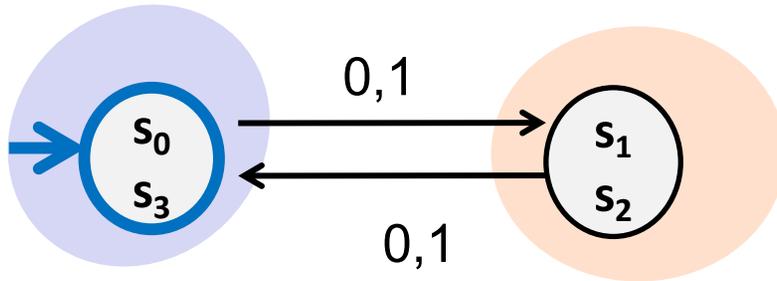

A Simpler Minimization Example

**Split states into
accept/reject groups**

**Every symbol causes
the DFA to go from one
group to the other so
neither group needs to
be split**

Minimized DFA

length is even

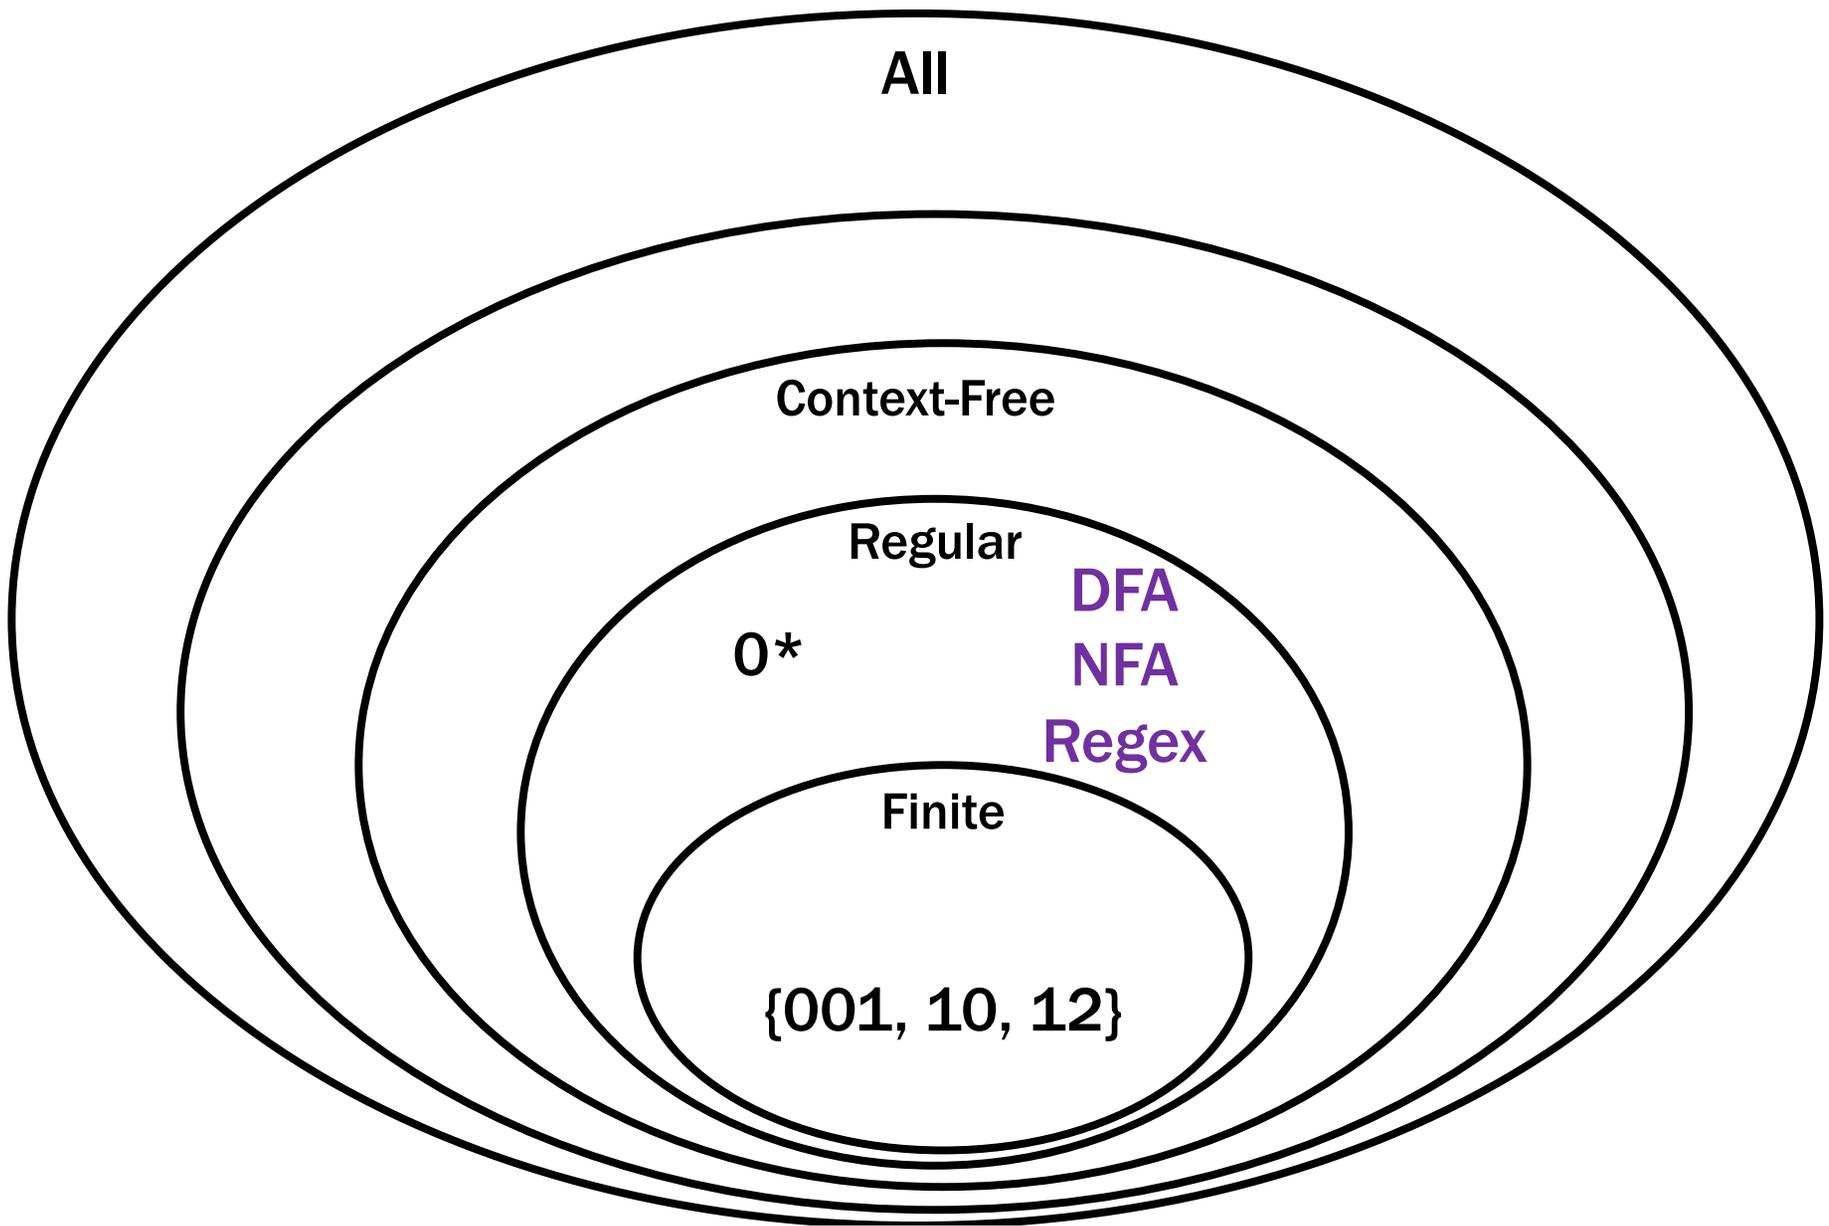

length is odd

The set of all binary strings with $\#$ of 1's \equiv $\#$ of 0's (mod 2).
= The set of all binary strings with even length.

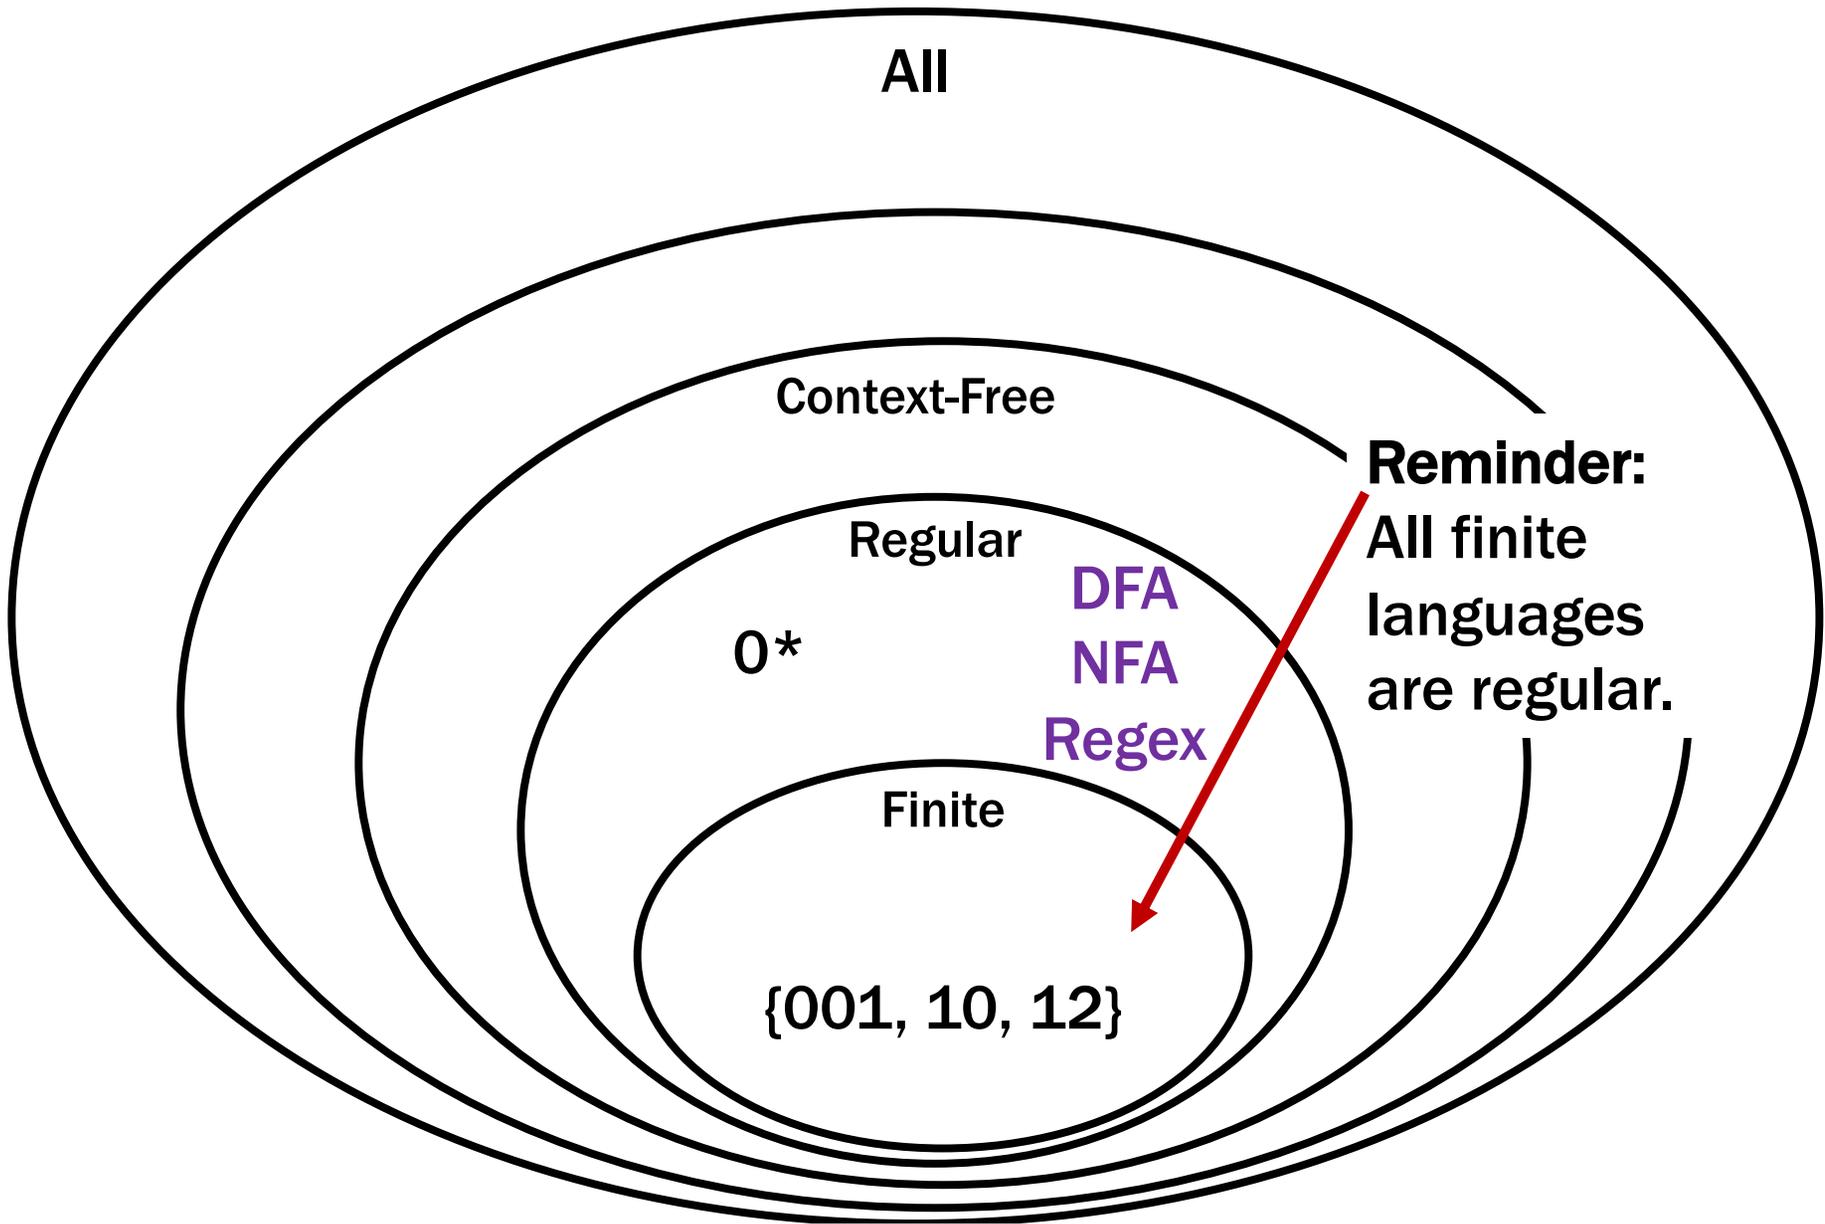

What languages have DFAs? CFGs?

All of them?

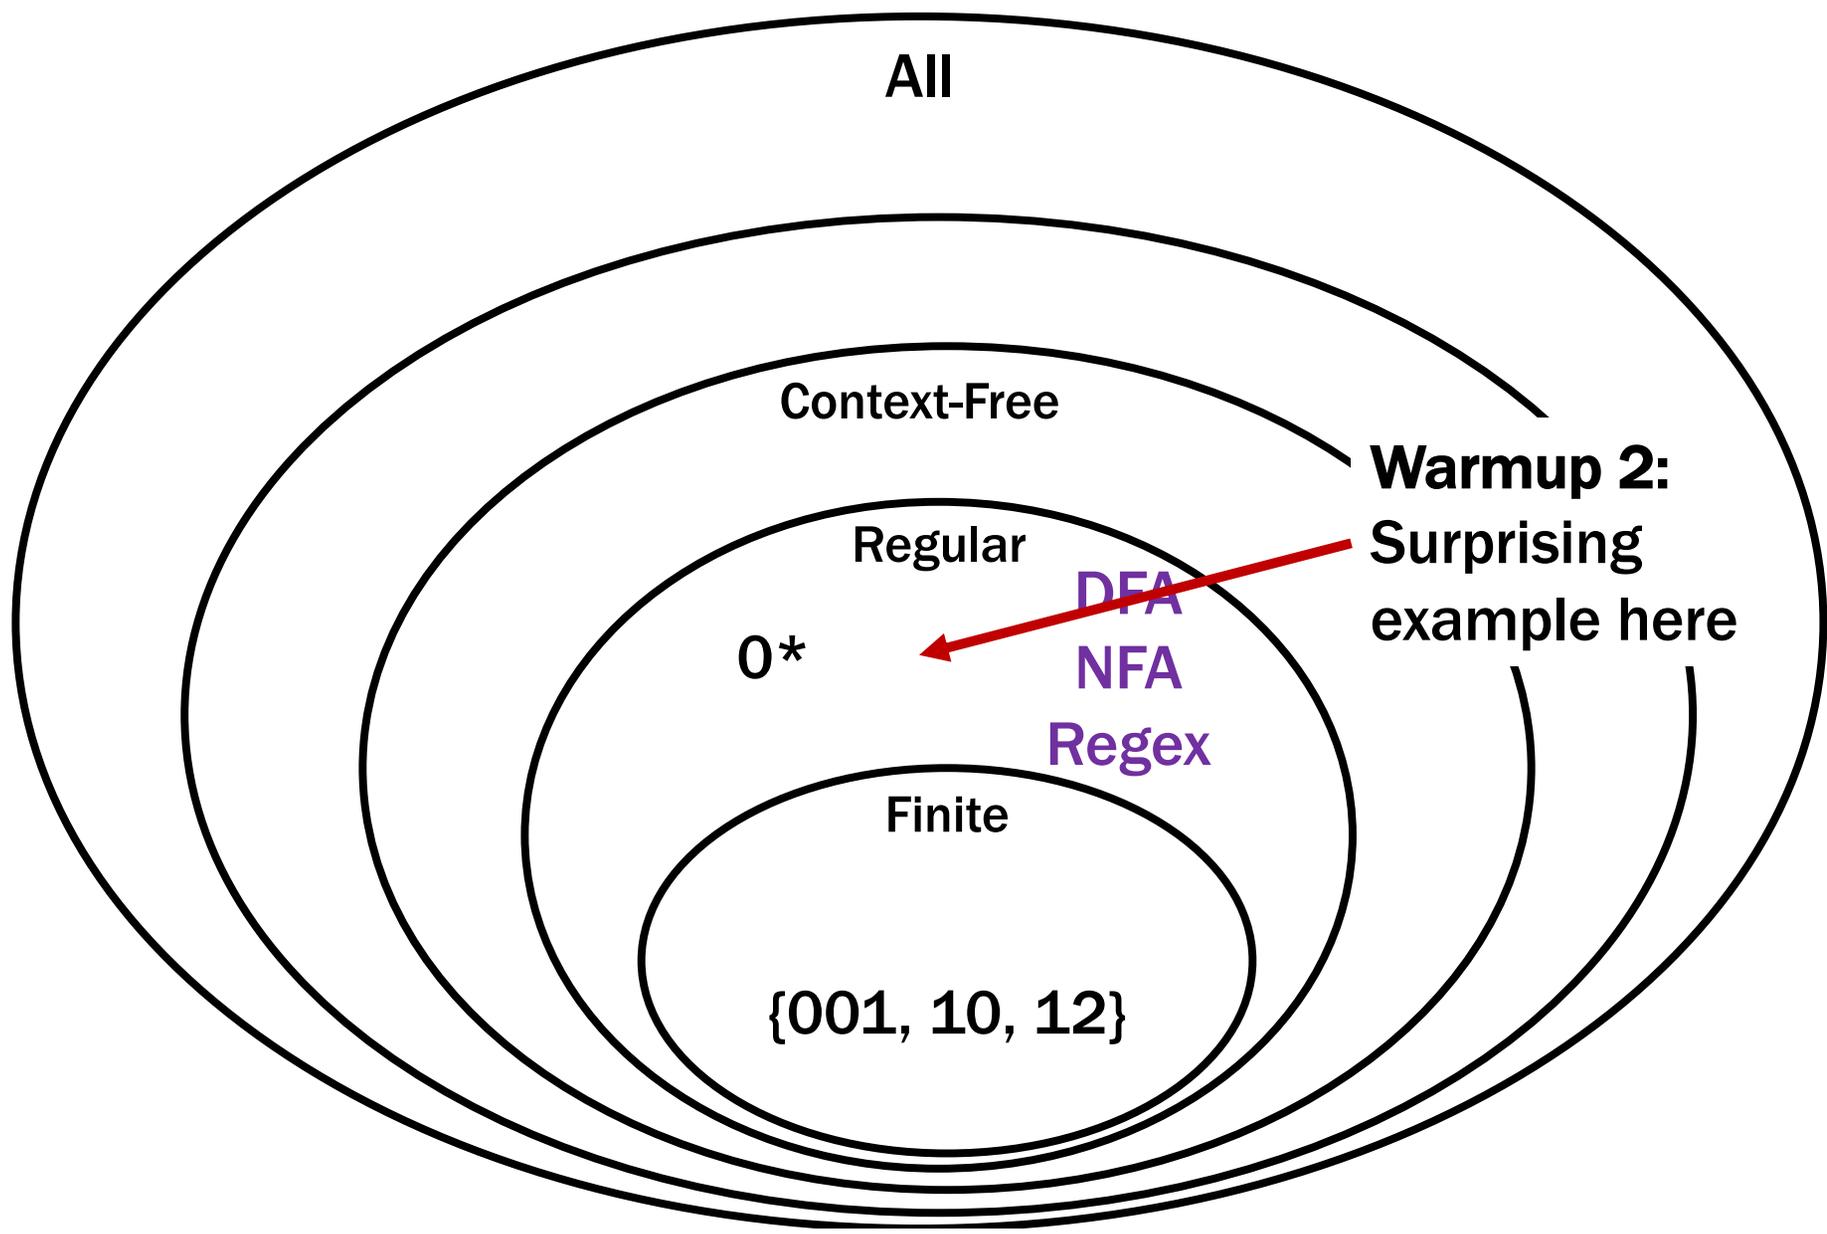

Languages and Representations!

Languages and Representations!

Languages and Machines!

An Interesting Infinite Regular Language

$L = \{x \in \{0, 1\}^* : x \text{ has an equal number of substrings } 01 \text{ and } 10\}$.

L is infinite.

0, 00, 000, ...

L is regular. How could this be?

That seems to require comparing counts...

- easy for a CFG
- but seems hard for DFAs!

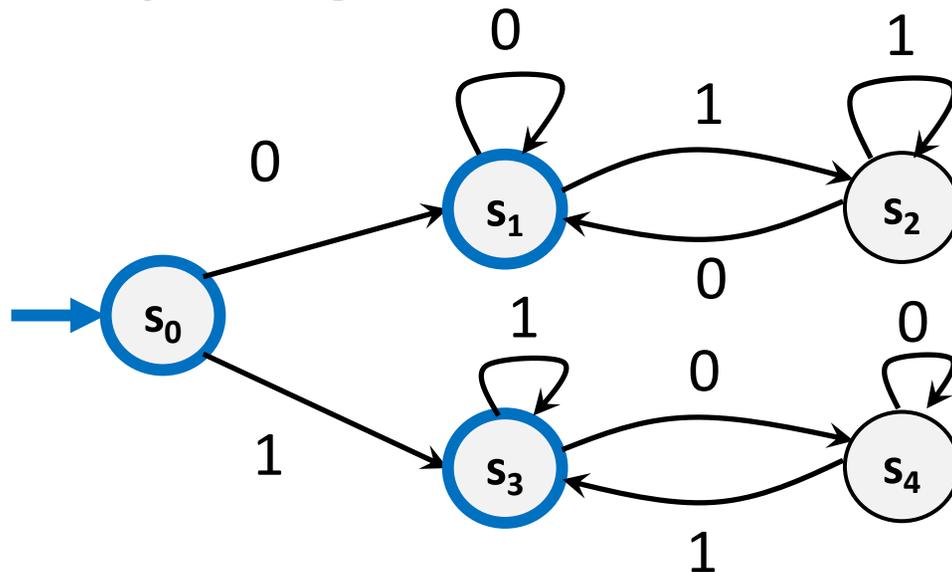

An Interesting Infinite Regular Language

$L = \{x \in \{0, 1\}^* : x \text{ has an equal number of substrings } 01 \text{ and } 10\}$.

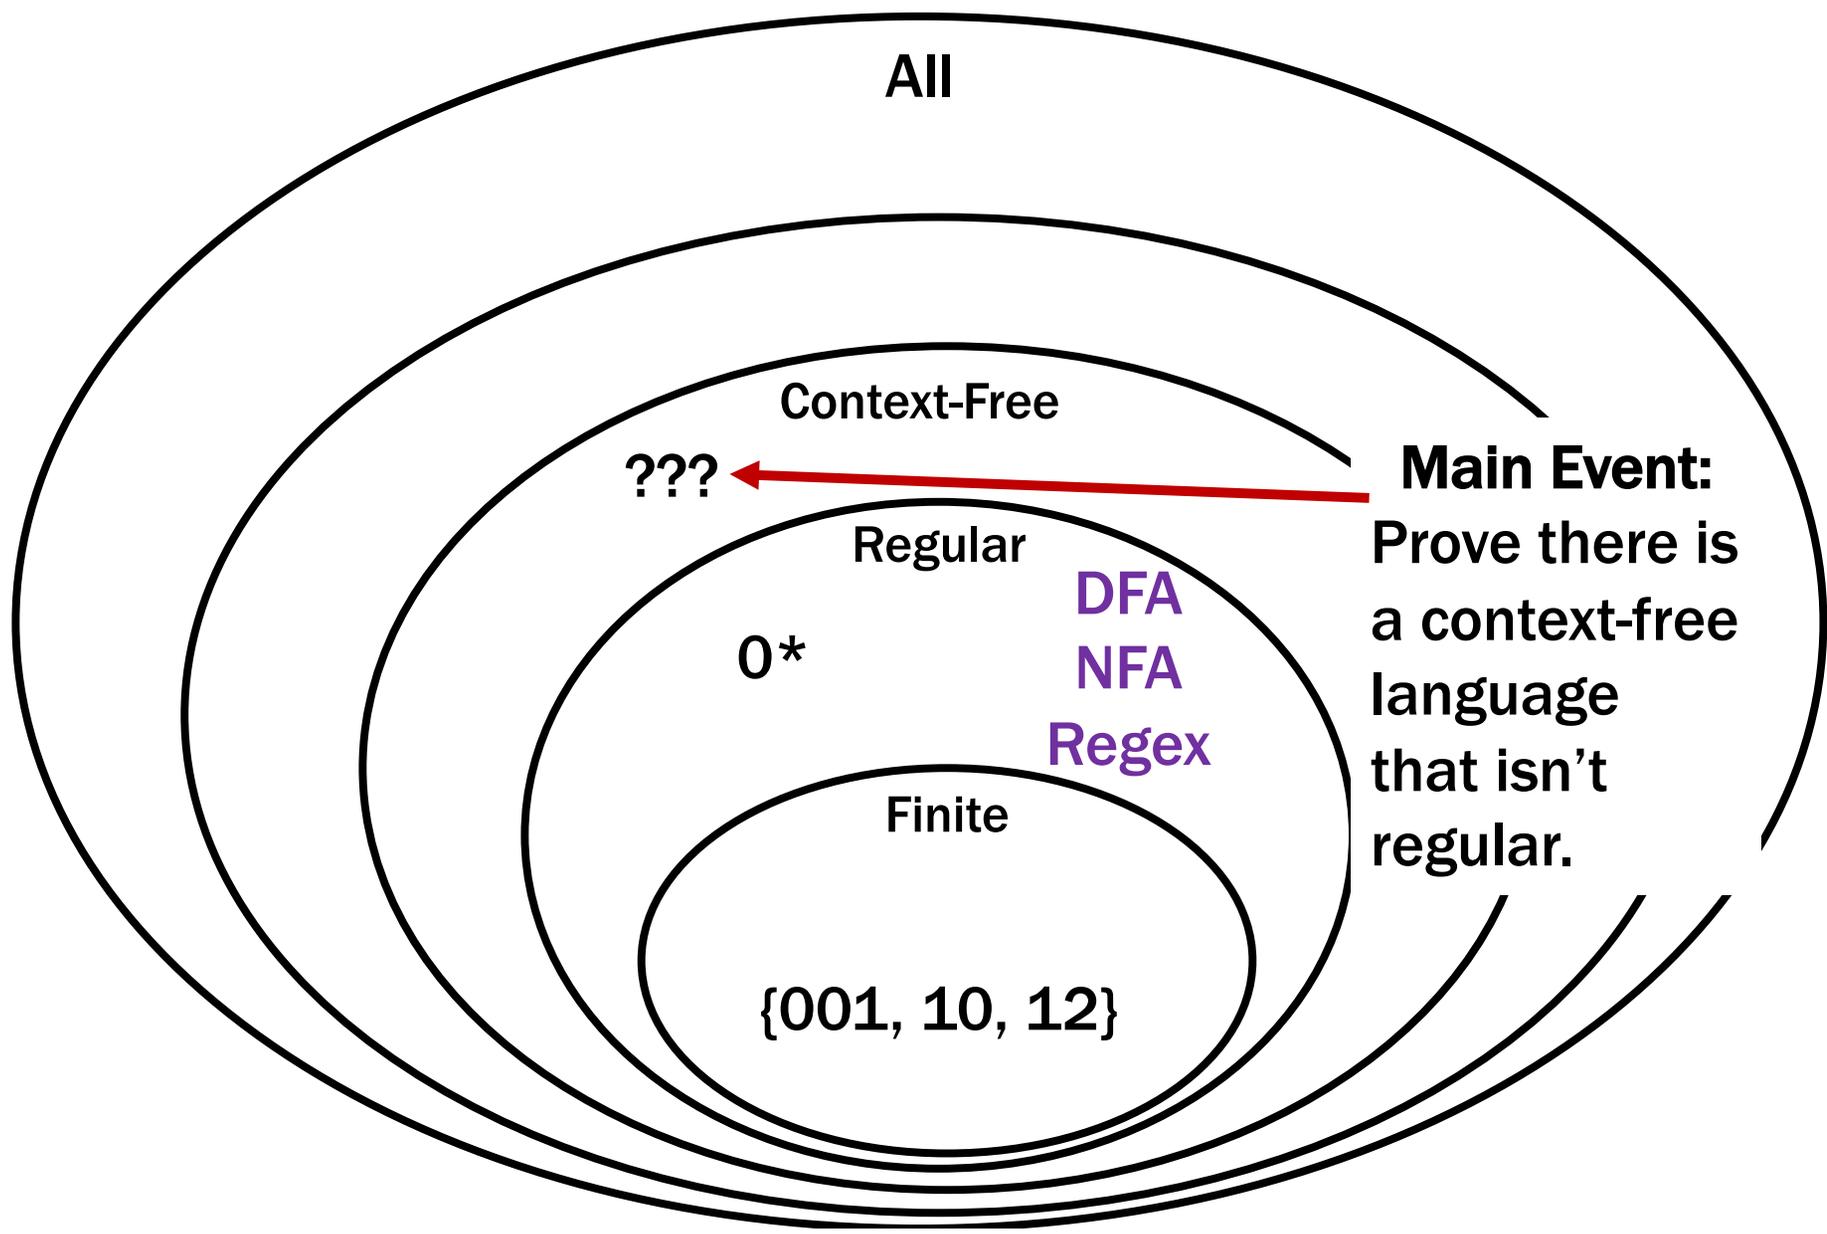

L is infinite.

0, 00, 000, ...

L is regular. How could this be? It is just the set of binary strings that are empty or begin and end with the same character!

Languages and Representations!

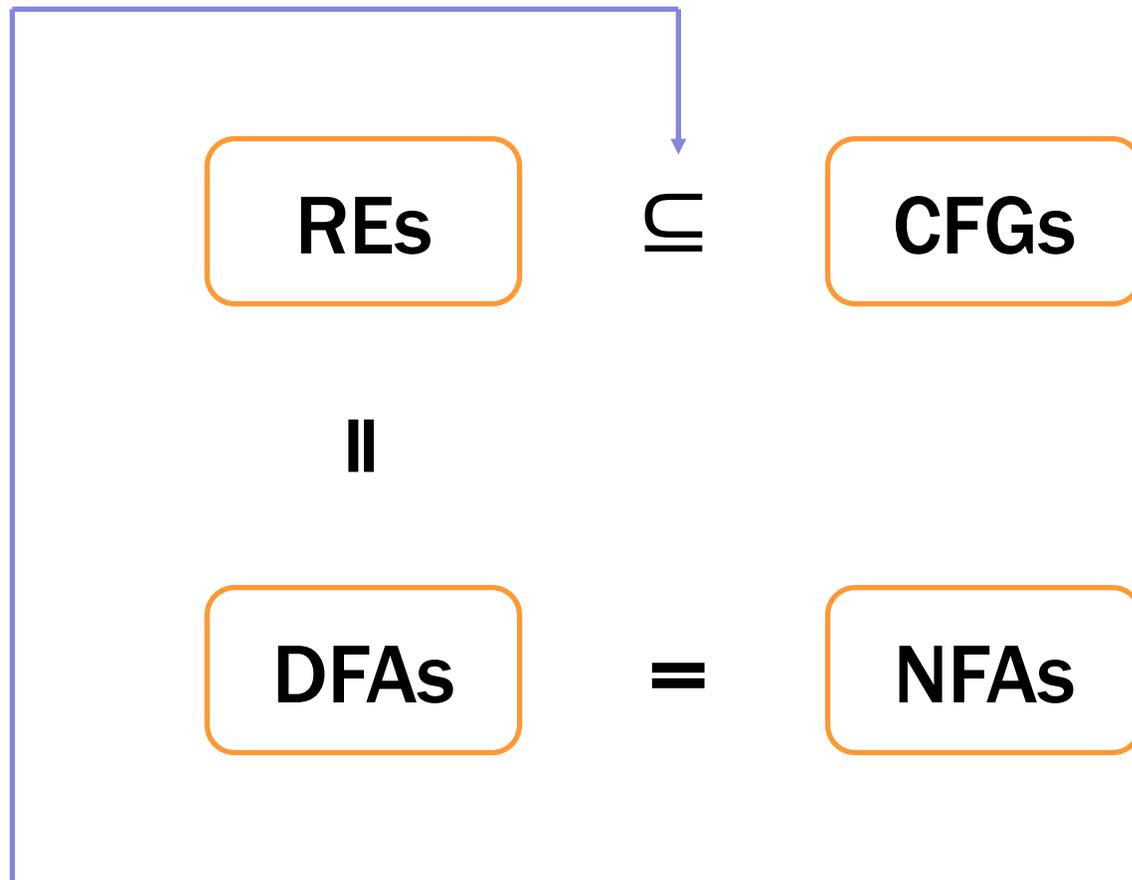

Main Event:
Prove there is a context-free language that isn't regular.

???

0^*

$\{001, 10, 12\}$

The story so far...

Now: Is this \subseteq really "=" or " \subsetneq "?

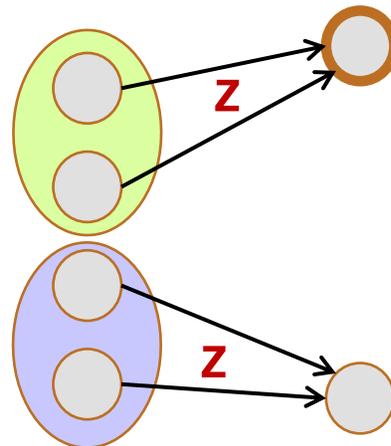

Recall: How to prove a DFA minimal?

- Found states that must be distinguished:
 - green and purple states cannot be collapsed or else the machine would make a mistake if *rest of string* is **z**

This works if we have a DFA.
But what if we do not
(e.g., if we have a CFG)

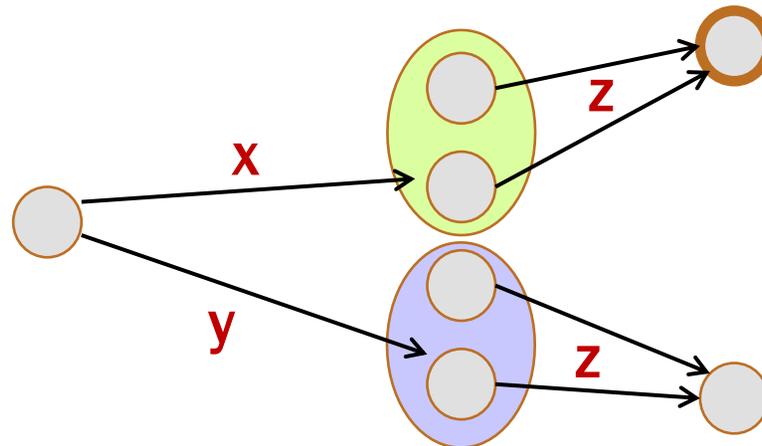

Instead of states, we can think
of the strings taken to that state

Indeed, we don't need all strings,
just one string taken to it is enough

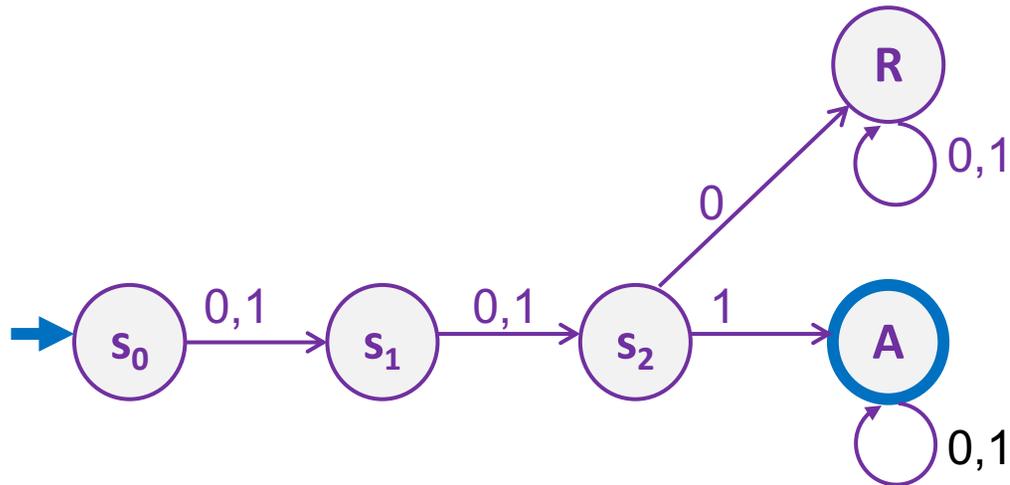

Recall: How to prove a DFA minimal?

- Found states that must be distinguished:
 - green and purple states cannot be collapsed or else the machine would make a mistake if *rest of string* is **x**

The completion **z** is proof that **x** and **y** cannot go to the same state (they must be distinguished)

Recall: Binary strings with a 1 in the 3rd position from the start

None of these states can be grouped!

Can turn this into an argument with strings...

ϵ goes to s_0

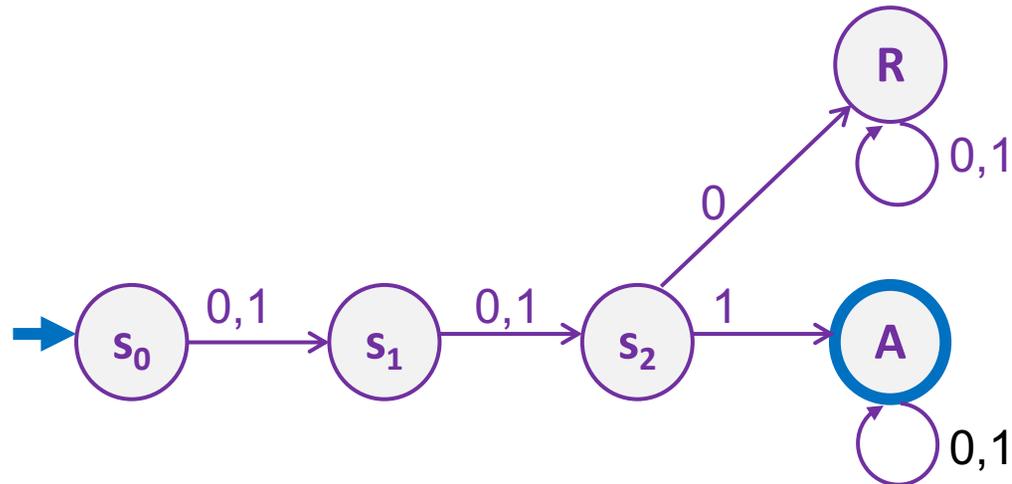

0 goes to s_1

001 goes to s_2

000 goes to R

001 goes to A

Recall: Binary strings with a 1 in the 3rd position from the start

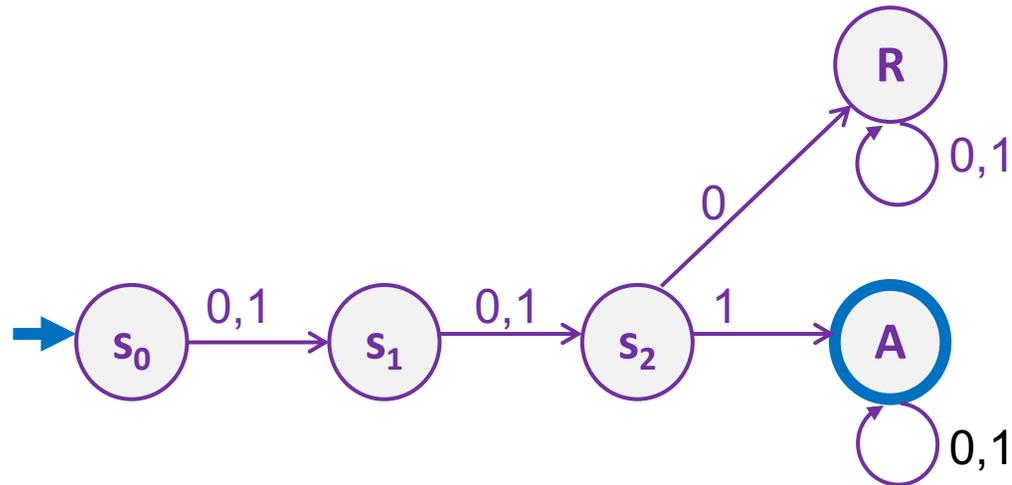

000 and **001** must be distinguished (in different states)

- if followed by ϵ , one is **rejected** and one is **accepted**
- same argument applies to **001** vs ϵ , **0**, **00**

00 and **000** must be distinguished (in different states)

- if followed by **1**, one is **rejected** and one is **accepted**
- similar arguments for the rest

Recall: Binary strings with a 1 in the 3rd position from the start

$\{\epsilon, 0, 00, 000, 001\}$ is a distinguishing set

- every pair must be distinguished (in different states)
some "rest of the string" makes one accepting and one rejecting
- any DFA needs at least 5 states

The language of “Binary Palindromes” is Context-Free

$$S \rightarrow \varepsilon \mid 0 \mid 1 \mid 0S0 \mid 1S1$$

Can prove this is not regular (**irregular**)
by finding an *infinite* distinguishing set!

B = {binary palindromes} can't be recognized by any DFA

Suppose for contradiction that some DFA, **M**, recognizes **B**.

We will show **M** accepts or rejects a string it shouldn't.

Consider $S = \{1, 01, 001, 0001, 00001, \dots\} = \{0^n1 : n \geq 0\}$.

Useful Lemmas about DFAs

Lemma 1: If DFA **M** has **n** states and a set **S** contains *more than n* strings, then **M** takes at least two strings from **S** to the same state.

M can't take $n+1$ or more strings to different states because it doesn't have $n+1$ different states.

So, some pair of strings must go to the same state.

B = {binary palindromes} can't be recognized by any DFA

Suppose for contradiction that some DFA, **M**, accepts **B**.

We will show **M** accepts or rejects a string it shouldn't.

Consider $S = \{1, 01, 001, 0001, 00001, \dots\} = \{0^n1 : n \geq 0\}$.

*Since there are finitely many states in **M** and infinitely many strings in S , by Lemma 1, there exist strings $0^a1 \in S$ and $0^b1 \in S$ with $a \neq b$ that end in the same state of **M**.*

SUPER IMPORTANT POINT: You do not get to choose what a and b are. Remember, we've just proven they exist...we must take the ones we're given!

B = {binary palindromes} can't be recognized by any DFA

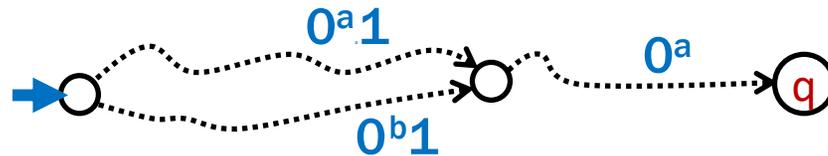

Suppose for contradiction that some DFA, **M**, accepts **B**.

We will show **M** accepts or rejects a string it shouldn't.

Consider $S = \{1, 01, 001, 0001, 00001, \dots\} = \{0^n1 : n \geq 0\}$.

Since there are finitely many states in **M** and infinitely many strings in S , by Lemma 2, there exist strings $0^a1 \in S$ and $0^b1 \in S$ with $a \neq b$ that end in the same state of **M**.

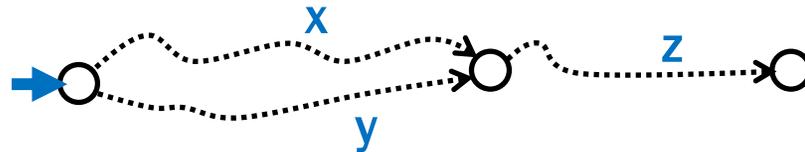

Now, consider appending 0^a to both strings.

Useful Lemmas about DFAs

Lemma 2: If DFA M takes $x, y \in \Sigma^*$ to the same state, then for every $z \in \Sigma^*$, M accepts $x \cdot z$ iff it accepts $y \cdot z$.

M can't remember if the input was x or y .

B = {binary palindromes} can't be recognized by any DFA

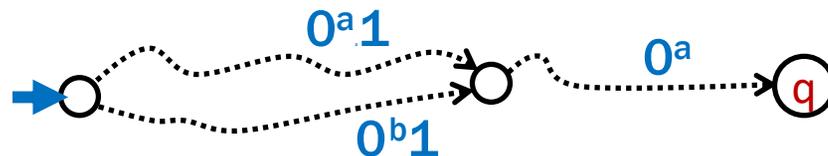

Suppose for contradiction that some DFA, **M**, accepts **B**.

We will show **M** accepts or rejects a string it shouldn't.

Consider $S = \{1, 01, 001, 0001, 00001, \dots\} = \{0^n1 : n \geq 0\}$.

Since there are finitely many states in **M** and infinitely many strings in S , by Lemma 2, there exist strings $0^a1 \in S$ and $0^b1 \in S$ with $a \neq b$ that end in the same state of **M**.

Now, consider appending 0^a to both strings.

Since 0^a1 and 0^b1 end in the same state, 0^a10^a and 0^b10^a also end in the same state, call it **q**. But then **M** makes a mistake: **q** needs to be an accept state since $0^a10^a \in B$, but **M** would accept $0^b10^a \notin B$, which is an error.

B = {binary palindromes} can't be recognized by any DFA

Suppose for contradiction that some DFA, **M**, accepts **B**.

We will show **M** accepts or rejects a string it shouldn't.

Consider $S = \{1, 01, 001, 0001, 00001, \dots\} = \{0^n1 : n \geq 0\}$.

Since there are finitely many states in **M** and infinitely many strings in S , by Lemma 2, there exist strings $0^a1 \in S$ and $0^b1 \in S$ with $a \neq b$ that end in the same state of **M**.

Now, consider appending 0^a to both strings.

Since 0^a1 and 0^b1 end in the same state, 0^a10^a and 0^b10^a also end in the same state, call it q . But then **M** makes a mistake: q needs to be an accept state since $0^a10^a \in B$, but **M** would accept $0^b10^a \notin B$, which is an error.

*This proves that **M** does not recognize **B**, contradicting our assumption that it does. Thus, no DFA recognizes **B**.*

Showing that a Language L is not regular

1. “Suppose for contradiction that some DFA M recognizes L .”
2. Consider an INFINITE set S of prefixes (which we intend to complete later).
3. “Since S is infinite and M has finitely many states, there must be two strings s_a and s_b in S for $s_a \neq s_b$ that end up at the same state of M .”
4. Consider appending the (correct) completion t to each of the two strings.
5. “Since s_a and s_b both end up at the same state of M , and we appended the same string t , both $s_a t$ and $s_b t$ end at the same state q of M . Since $s_a t \in L$ and $s_b t \notin L$, M does not recognize L .”
6. “Thus, no DFA recognizes L .”

Showing that a Language **L** is not regular

The choice of **S** is the creative part of the proof

You must find an infinite set **S** with the property that *no two* strings can be taken to the same state

- i.e., for *every pair* of strings **S** there is a "rest of the string" that makes one accepting and one rejecting

Prove $A = \{0^n 1^n : n \geq 0\}$ is not regular

Suppose for contradiction that some DFA, M , recognizes A .

Let $S =$

Prove $A = \{0^n 1^n : n \geq 0\}$ is not regular

Suppose for contradiction that some DFA, **M**, recognizes **A**.

Let **S** = $\{0^n : n \geq 0\}$. Since **S** is infinite and **M** has finitely many states, there must be two strings, 0^a and 0^b for some $a \neq b$ that end in the same state in **M**.

Prove $A = \{0^n 1^n : n \geq 0\}$ is not regular

Suppose for contradiction that some DFA, M , recognizes A .

Let $S = \{0^n : n \geq 0\}$. Since S is infinite and M has finitely many states, there must be two strings, 0^a and 0^b for some $a \neq b$ that end in the same state in M .

Consider appending 1^a to both strings.

Prove $A = \{0^n 1^n : n \geq 0\}$ is not regular

Suppose for contradiction that some DFA, M , recognizes A .

Let $S = \{0^n : n \geq 0\}$. Since S is infinite and M has finitely many states, there must be two strings, 0^a and 0^b for some $a \neq b$ that end in the same state in M .

Consider appending 1^a to both strings.

Note that $0^a 1^a \in A$, but $0^b 1^a \notin A$ since $a \neq b$. But they both end up in the same state of M , call it q . Since $0^a 1^a \in A$, state q must be an accept state but then M would incorrectly accept $0^b 1^a \notin A$ so M does not recognize A .

Thus, no DFA recognizes A .

Prove $P = \{\text{balanced parentheses}\}$ is not regular

Suppose for contradiction that some DFA, M , accepts P .

Let $S =$

Prove $P = \{\text{balanced parentheses}\}$ is not regular

Suppose for contradiction that some DFA, M , recognizes P .

Let $S = \{(^n : n \geq 0)\}$. Since S is infinite and M has finitely many states, there must be two strings, $(^a$ and $(^b$ for some $a \neq b$ that end in the same state in M .

Prove $P = \{\text{balanced parentheses}\}$ is not regular

Suppose for contradiction that some DFA, M , recognizes P .

Let $S = \{(^n : n \geq 0)\}$. Since S is infinite and M has finitely many states, there must be two strings, $(^a$ and $(^b$ for some $a \neq b$ that end in the same state in M .

Consider appending $)^a$ to both strings.

Prove $P = \{\text{balanced parentheses}\}$ is not regular

Suppose for contradiction that some DFA, M , recognizes P .

Let $S = \{(^n : n \geq 0)\}$. Since S is infinite and M has finitely many states, there must be two strings, $(^a$ and $(^b$ for some $a \neq b$ that end in the same state in M .

Consider appending $)^a$ to both strings.

Note that $(^a)^a \in P$, but $(^b)^a \notin P$ since $a \neq b$. But they both end up in the same state of M , call it q . Since $(^a)^a \in P$, state q must be an accept state but then M would incorrectly accept $(^b)^a \notin P$ so M does not recognize P .

Thus, no DFA recognizes P .

Showing that a Language L is not regular

1. “Suppose for contradiction that some DFA M recognizes L .”
2. Consider an INFINITE set S of prefixes (which we intend to complete later). It is imperative that for *every pair* of strings in our set there is an “accept” completion that the two strings DO NOT SHARE.
3. “Since S is infinite and M has finitely many states, there must be two strings s_a and s_b in S for $s_a \neq s_b$ that end up at the same state of M .”
4. Consider appending the (correct) completion t to each of the two strings.
5. “Since s_a and s_b both end up at the same state of M , and we appended the same string t , both $s_a t$ and $s_b t$ end at the same state q of M . Since $s_a t \in L$ and $s_b t \notin L$, M does not recognize L .”
6. “Thus, no DFA recognizes L .”

Distinguishing Sets

- Not necessary that our construction can generate **every** string in the language
- Examples:
 - palindromes: only generated those of the form 0^n10^n
 - balanced parentheses: only generated $(^n)^n$
- Sufficient to find a "core" set of strings whose prefixes must be distinguished
 - this becomes our distinguishing set

Recall: Prove $L = \{0^n 1^n : n \geq 0\}$ is not regular

Suppose for contradiction that some DFA, M , recognizes L .

Let $S = \{0^n : n \geq 0\}$. Since S is infinite and M has finitely many states, there must be two strings, 0^a and 0^b for some $a \neq b$ that end in the same state in M .

Consider appending 1^a to both strings.

Note that $0^a 1^a \in L$, but $0^b 1^a \notin L$ since $a \neq b$. But they both end up in the same state of M , call it q . Since $0^a 1^a \in L$, state q must be an accept state but then M would incorrectly accept $0^b 1^a \notin L$ so M does not recognize L .

Thus, no DFA recognizes L .

Prove $U = \{0^n 1^m : m \geq n \geq 0\}$ is not regular

- This is a superset: $L \subseteq U$
- Even though U is a bigger set, all we need to do is find an **infinite** set of strings that must be distinguished
 - we don't have to show that all strings in U must be distinguished
- The same strings still need to be distinguished:

$$S = \{0^n : n \geq 0\} = \{\epsilon, 0, 00, 000, \dots\}$$

Let $x, y \in S$ be arbitrary. Suppose that $x \neq y$.

By the definition of S , $x = 0^a$ and $y = 0^b$ for some $a \neq b$.

Consider $z = 1^{\min(a,b)}$

Important Notes

- It is not necessary for our strings xz with $x \in L$ to allow any string in the language
 - we only need to find some infinite set of strings that must be distinguished by the machine
- It is not true that, if L is irregular and $L \subseteq U$, then U is irregular!
 - we always have $L \subseteq \{0,1\}^*$ and $\{0,1\}^*$ is regular!

Proving $\{0,1\}^*$ is not regular fails!

$$S = \{0^n : n \geq 0\} = \{\epsilon, 0, 00, 000, \dots\}$$

Why is this no longer a distinguishing set?

Let $x, y \in S$ be arbitrary. Suppose that $x \neq y$.

By the definition of S , $x = 0^a$ and $y = 0^b$ for some $a, b \geq 0$.

Note that we must have $a \neq b$. (Otherwise, we would have $x = y$.)

Consider $z = 1^a$. We can see that $x \cdot z = 0^a 1^a \in \{0,1\}^*$ (since $a = a$) and $y \cdot z = 0^b 1^a \notin \{0,1\}^*$ since $(b \neq a)$.

No longer true that $0^b 1^a \notin \{0,1\}^*$!

Important Notes

- It is not necessary for our strings xz with $x \in L$ to allow any string in the language
 - we only need to find a small “core” set of strings that must be distinguished by the machine
- It is not true that, if L is irregular and $L \subseteq U$, then U is irregular!
 - we always have $L \subseteq \Sigma^*$ and Σ^* is regular!
 - our argument needs different answers: $(xz \in L) \neq (yz \in L)$
and for Σ^* , both strings are always in the language

Do not claim in your proof that,
because $L \subseteq U$, U is also irregular
