

tail bounds

Often, we want to bound the probability that a random variable X is far from its expectation.

A random variable X has mean μ

Can we bound

$$Pr(X \geq 100\mu)$$

$$Pr(X \geq 1,000\mu)$$

$$Pr(X \geq 1,000,000\mu)$$

Not without additional information...

We know that randomized quicksort runs in $O(n \log n)$ *expected* time. But what's the probability that it takes more than $10 n \log(n)$ steps? More than $n^{1.5}$ steps?

If we know the expected advertising cost is \$1500/day, what's the probability we go over budget? By a factor of 4?

We only expect 10,000 homeowners to default on their mortgages. What's the probability that 1,000,000 homeowners default?

the lake wobegon effect

“Lake Wobegon, Minnesota, where
all the women are strong,
all the men are good looking,
and
all the children are above average...”

An *arbitrary* random variable could have very bad behavior. But knowledge is power; if we know *something*, can we bound the badness?

Suppose we know that X is always non-negative.

Theorem: If X is a non-negative random variable, then for every $\alpha > 0$, we have

$$P(X \geq \alpha) \leq \frac{E[X]}{\alpha}$$

Corr:

$$P(X \geq \alpha E[X]) \leq 1/\alpha$$

Theorem: If X is a non-negative random variable, then for every $\alpha > 0$, we have

$$P(X \geq \alpha) \leq \frac{E[X]}{\alpha}$$

Example: if $X =$ time to quicksort n items, expectation $E[X] \approx 1.4 n \log n$. What's probability that it takes > 4 times as long as expected?

By Markov's inequality:

$$P(X \geq 4 \cdot E[X]) \leq E[X]/(4 E[X]) = 1/4$$

Theorem: If X is a non-negative random variable, then for every $\alpha > 0$, we have

$$P(X \geq \alpha) \leq \frac{E[X]}{\alpha}$$

Proof:

$$\begin{aligned} E[X] &= \sum_x xP(x) \\ &= \sum_{x < \alpha} xP(x) + \sum_{x \geq \alpha} xP(x) \\ &\geq 0 + \sum_{x \geq \alpha} \alpha P(x) \quad (x \geq 0; \alpha \leq x) \\ &= \alpha P(X \geq \alpha) \end{aligned}$$

Markov's inequality

Theorem: If X is a non-negative random variable, then for any $\alpha > 0$ we have

Proof:

$$E[X]$$

$$=$$
$$\geq$$

$$= \alpha P(X \geq \alpha)$$

$$= \int_{\alpha}^{\infty} f(x) dx$$

$$(x \geq 0; \alpha \leq x)$$

For a random variable X , the *tails* of X are the parts of the PMF that are “far” from its mean.

Binomial distribution, $n=100$, $p=.5$

heavy-tailed distribution

Chebyshev's inequality

If we know *more* about a random variable, we can often use that to get *better* tail bounds.

Suppose we *also* know the variance.

Theorem: If Y is an arbitrary random variable with $E[Y] = \mu$, then, for any $\alpha > 0$,

$$P(|Y - \mu| \geq \alpha) \leq \frac{\text{Var}[Y]}{\alpha^2}$$

Chebyshev's inequality

Theorem: If Y is an arbitrary random variable with $\mu = E[Y]$, then, for any $\alpha > 0$,

$$P(|Y - \mu| \geq \alpha) \leq \frac{\text{Var}[Y]}{\alpha^2}$$

Proof: Let $X = (Y - \mu)^2$

X is non-negative, so we can apply Markov's inequality:

$$\begin{aligned} P(|Y - \mu| \geq \alpha) &= P(X \geq \alpha^2) \\ &\leq \frac{E[X]}{\alpha^2} = \frac{\text{Var}[Y]}{\alpha^2} \end{aligned}$$

Chebyshev's inequality

Theorem: If Y is an arbitrary random variable with mean μ and variance σ^2 , and $\alpha > 0$,

$$P(|Y - \mu| \geq \alpha) \leq \frac{\text{Var}[Y]}{\alpha^2}$$

Proof: Let $X = (Y - \mu)^2$. X is non-negative. Markov's inequality:

$$P(|Y - \mu| \geq \alpha) = P(X \geq \alpha^2) \leq \frac{E[X]}{\alpha^2} = \frac{\text{Var}[Y]}{\alpha^2}$$

Chebyshev's inequality

Theorem: If Y is an arbitrary random variable with $\mu = E[Y]$, then, for any $\alpha > 0$,

$$P(|Y - \mu| \geq \alpha) \leq \frac{\text{Var}[Y]}{\alpha^2}$$

Corr: If

$$\sigma = SD[Y] = \sqrt{\text{Var}[Y]}$$

Then:

$$P(|Y - \mu| \geq t\sigma) \leq \frac{\sigma^2}{t^2\sigma^2} = \frac{1}{t^2}$$

Chebyshev's inequality

$$P(|Y - \mu| \geq t\sigma) \leq \frac{1}{t^2}$$

Chebyshev's inequality

$$P(|Y - \mu| \geq \alpha) \leq \frac{\text{Var}[Y]}{\alpha^2}$$

$Y =$ comparisons in quicksort for $n=1024$

$$E[Y] = 1.4 n \log_2 n \approx 14000$$

$$\text{Var}[Y] = ((21-2\pi^2)/3)*n^2 \approx 441000$$

(i.e. $SD[Y] \approx 664$)

$$P(Y \geq 4\mu) = P(Y - \mu \geq 3\mu) \leq \text{Var}(Y)/(9\mu^2) < .000242$$

1000 times smaller than Markov

but still overestimated?: $\sigma/\mu \approx 0.05$, so $4\mu \approx \mu + 60\sigma$

Suppose $X \sim \text{Bin}(n, p)$

$$\mu = E[X] = pn$$

Chernoff bound:

For any δ with $0 < \delta < 1$,

$$P(X > (1 + \delta)\mu) \leq e^{-\frac{\delta^2 \mu}{2}}$$

$$P(X < (1 - \delta)\mu) \leq e^{-\frac{\delta^2 \mu}{3}}$$

Suppose $X \sim \text{Bin}(n, p)$

$\mu = E[X] = np$

Chernoff bound

For any $\delta \in (0, 1)$

$$P(X \geq (1 + \delta)\mu)$$

$$P(X \leq (1 - \delta)\mu)$$

$$\leq e^{-\frac{\delta^2 \mu}{2}}$$

$$\leq e^{-\frac{\delta^2 \mu}{3}}$$

router buffers

Model: 100,000 computers each independently send a packet with probability $q = 0.01$ each second. The router processes its buffer every second. How many packet buffers so that router drops a packet:

- Never?

100,000

- With probability at most 10^{-6} , every hour?

1210

- With probability at most 10^{-6} , every year?

1250

- With probability at most 10^{-6} , since Big Bang?

1331

$X \sim \text{Bin}(100,000, 0.01)$, $\mu = E[X] = 1000$

Let p = probability of buffer overflow in 1 second

By the Chernoff bound

$$p = P(X > (1 + \delta)\mu) \leq e^{-\frac{\delta^2 \mu}{2}}$$

Overflow probability in T seconds

$$= 1 - (1-p)^T \leq Tp \leq T \exp(-\delta^2 \mu / 2),$$

which is $\leq \varepsilon$ provided $\delta \geq \sqrt{(2/\mu) \ln(T/\varepsilon)}$.

For $\varepsilon = 10^{-6}$ per hour: $\delta \approx .210$, buffers = 1210

For $\varepsilon = 10^{-6}$ per year: $\delta \approx .250$, buffers = 1250

For $\varepsilon = 10^{-6}$ per 15BY: $\delta \approx .331$, buffers = 1331

Tail bounds – bound probabilities of extreme events

Three (of many):

Markov: $P(X \geq k \mu) \leq 1/k$ (weak, but general; only need $X \geq 0$ and μ)

Chebyshev: $P(|X - \mu| \geq k \sigma) \leq 1/k^2$ (often stronger, but also need σ)

Chernoff: various forms, depending on underlying distribution;
usually $1/\text{exponential}$, vs $1/\text{polynomial}$ above

Generally, more assumptions/knowledge \Rightarrow better bounds

“Better” than exact distribution?

Maybe, e.g. if latter is unknown or mathematically messy

“Better” than, e.g., “Poisson approx to Binomial”?

Maybe, e.g. if you need rigorously “ \leq ” rather than just “ \approx ”
