

---

# random variables

let  $X_i =$  index of

A *random variable*  $X$  assigns a real number to each outcome in a probability space.

Ex.

Let  $H$  be the number of Heads when 20 coins are tossed

Let  $T$  be the total of 2 dice rolls

Let  $X$  be the number of coin tosses needed to see 1<sup>st</sup> head

Note; even if the underlying experiment has “equally likely outcomes,” the associated random variable may not

<i>Outcome</i>	$H$	$P(H)$
TT	0	$P(H=0) = 1/4$
TH	1	} $P(H=1) = 1/2$
HT	1	
HH	2	$P(H=2) = 1/4$

20 balls numbered 1, 2, ..., 20

Draw 3 without replacement

Let  $X$  = the maximum of the numbers on those 3 balls

What is  $P(X \geq 17)$

$$P(X = 20) = \binom{19}{2} / \binom{20}{3} = \frac{3}{20} = 0.150$$

$$P(X = 19) = \binom{18}{2} / \binom{20}{3} = \frac{18 \cdot 17 / 2!}{20 \cdot 19 \cdot 18 / 3!} \approx 0.134$$

⋮

$$\sum_{i=17}^{20} P(X = i) \approx 0.508$$

Alternatively:

$$P(X \geq 17) = 1 - P(X < 17) = 1 - \binom{16}{3} / \binom{20}{3} \approx 0.508$$

Flip a (biased) coin repeatedly until 1<sup>st</sup> head observed

How many flips? Let  $X$  be that number.

$$P(X=1) = P(H) = p$$

$$P(X=2) = P(TH) = (1-p)p$$

$$P(X=3) = P(TTH) = (1-p)^2p$$

...

Check that it is a valid probability distribution:

$$P\left(\bigcup_{i \geq 1} \{X = i\}\right) = \sum_{i \geq 1} (1-p)^{i-1}p = p \sum_{i \geq 0} (1-p)^i = p \frac{1}{1 - (1-p)} = 1$$

A *discrete* random variable is one taking on a countable number of possible values.

Ex:

$X = \text{sum of 3 dice, } 3 \leq X \leq 18, X \in \mathbb{N}$

$Y = \text{index of 1}^{\text{st}} \text{ head in seq of coin flips, } 1 \leq Y, Y \in \mathbb{N}$

$Z = \text{largest prime factor of } (1+Y), Z \in \{2, 3, 5, 7, 11, \dots\}$

If  $X$  is a discrete random variable taking on values from a countable set  $T \subseteq \mathbb{R}$ , then

$$p(a) = \begin{cases} P(X = a) & \text{for } a \in T \\ 0 & \text{otherwise} \end{cases}$$

is called the *probability mass function*. Note:  $\sum_{a \in T} p(a) = 1$

Let  $X$  be the number of heads observed in  $n$  coin flips

$$P(X = k) = \binom{n}{k} p^k (1 - p)^{n-k}, \text{ where } p = P(H)$$

Probability mass function:

## cumulative distribution function

The *cumulative distribution function* for a random variable  $X$  is the function  $F: \mathbb{R} \rightarrow [0, 1]$  defined by

$$F(a) = P[X \leq a]$$

Ex: if  $X$  has **probability mass function** given by:

$$p(1) = \frac{1}{4} \quad p(2) = \frac{1}{2} \quad p(3) = \frac{1}{8} \quad p(4) = \frac{1}{8}$$

$$F(a) = \begin{cases} 0 & a < 1 \\ \frac{1}{4} & 1 \leq a < 2 \\ \frac{3}{4} & 2 \leq a < 3 \\ \frac{7}{8} & 3 \leq a < 4 \\ 1 & 4 \leq a \end{cases}$$

NB: for discrete random variables, be careful about “ $\leq$ ” vs “ $<$ ”

For a discrete r.v.  $X$  with p.m.f.  $p(\bullet)$ , the *expectation of  $X$* , aka *expected value* or *mean*, is

$$E[X] = \sum_x xp(x)$$

average of random values, weighted by their respective probabilities

For the equally-likely outcomes case, this is just the average of the possible random values of  $X$

For *unequally-likely* outcomes, it is again the average of the possible random values of  $X$ , **weighted by their respective probabilities**

Ex 1: Let  $X$  = value seen rolling a fair die  $p(1), p(2), \dots, p(6) = 1/6$

$$E[X] = \sum_{i=1}^6 ip(i) = \frac{1}{6}(1 + 2 + \dots + 6) = \frac{21}{6} = 3.5$$

Ex 2: Coin flip;  $X = +1$  if H (win \$1),  $-1$  if T (lose \$1)

$$E[X] = (+1) \cdot p(+1) + (-1) \cdot p(-1) = 1 \cdot (1/2) + (-1) \cdot (1/2) = 0$$

For a discrete r.v.  $X$  with p.m.f.  $p(\bullet)$ , the *expectation of  $X$* , aka *expected value* or *mean*, is

$$E[X] = \sum_x xp(x)$$

average of random values, weighted  
by their respective probabilities

**Another view:** A gambling game. If  $X$  is how much you win playing the game once, how much would you expect to win, on average, per game when repeatedly playing?

Ex 1: Let  $X$  = value seen rolling a fair die  $p(1), p(2), \dots, p(6) = 1/6$

If you win  $X$  dollars for that roll, how much do you expect to win?

$$E[X] = \sum_{i=1}^6 ip(i) = \frac{1}{6}(1 + 2 + \dots + 6) = \frac{21}{6} = 3.5$$

Ex 2: Coin flip;  $X = +1$  if H (win \$1),  $-1$  if T (lose \$1)

$$E[X] = (+1) \cdot p(+1) + (-1) \cdot p(-1) = 1 \cdot (1/2) + (-1) \cdot (1/2) = 0$$

“a fair game”: in repeated play you expect to win as much as you lose. Long term net gain/loss = 0.

Let  $X$  be the number of flips up to & including 1<sup>st</sup> head observed in repeated flips of a biased coin. If I pay you \$1 per flip, how much money would you expect to make?

$$P(H) = p; \quad P(T) = 1 - p = q$$

$$p(i) = pq^{i-1}$$

$$E(x) = \sum_{i \geq 1} ip(i) = \sum_{i \geq 1} ipq^{i-1} = p \sum_{i \geq 1} iq^{i-1} \quad (*)$$

A calculus trick:

$$\sum_{i \geq 1} iy^{i-1} = \sum_{i \geq 1} \frac{d}{dy} y^i = \sum_{i \geq 0} \frac{d}{dy} y^i = \frac{d}{dy} \sum_{i \geq 0} y^i = \frac{d}{dy} \frac{1}{1-y} = \frac{1}{(1-y)^2}$$

So (\*) becomes:

$$E[X] = p \sum_{i \geq 1} iq^{i-1} = \frac{p}{(1-q)^2} = \frac{p}{p^2} = \frac{1}{p}$$

E.g.:

$p=1/2$ ; on average head every 2<sup>nd</sup> flip  
 $p=1/10$ ; on average, head every 10<sup>th</sup> flip.

How much would you pay to play?

## expectation of a *function* of a random variable

Calculating  $E[g(X)]$ :

$Y=g(X)$  is a new r.v. Calc  $P[Y=j]$ , then apply defn:

$X = \text{sum of 2 dice rolls}$

$Y = g(X) = X \bmod 5$

$i$	$p(i) = P[X=i]$	$i \cdot p(i)$
2	1/36	2/36
3	2/36	6/36
4	3/36	12/36
5	4/36	20/36
6	5/36	30/36
7	6/36	42/36
8	5/36	40/36
9	4/36	36/36
10	3/36	30/36
11	2/36	22/36
12	1/36	12/36

$j$	$q(j) = P[Y = j]$	$j \cdot q(j)$
0	4/36+3/36 = 7/36	0/36
1	5/36+2/36 = 7/36	7/36
2	1/36+6/36+1/36 = 8/36	16/36
3	2/36+5/36 = 7/36	21/36
4	3/36+4/36 = 7/36	28/36

$$E[Y] = \sum_j j q(j) = \frac{72}{36} = 2$$

$$E[X] = \sum_i i p(i) = \frac{252}{36} = 7$$

## expectation of a *function* of a random variable

Calculating  $E[g(X)]$ : Another way – add in a different order, using  $P[X=...]$  instead of calculating  $P[Y=...]$

$X = \text{sum of 2 dice rolls}$

$i$	$p(i) = P[X=i]$	$g(i) \cdot p(i)$
2	1/36	2/36
3	2/36	6/36
4	3/36	12/36
5	4/36	0/36
6	5/36	5/36
7	6/36	12/36
8	5/36	15/36
9	4/36	16/36
10	3/36	0/36
11	2/36	2/36
12	1/36	2/36

$Y = g(X) = X \text{ mod } 5$

$j$	$q(j) = P[Y = j]$	$j \cdot q(j)$
0	$4/36 + 3/36 = 7/36$	0/36
1	$5/36 + 2/36 = 7/36$	7/36
2	$1/36 + 6/36 + 1/36 = 8/36$	16/36
3	$2/36 + 5/36 = 7/36$	21/36
4	$3/36 + 4/36 = 7/36$	28/36

$$E[Y] = \sum_j j q(j) = \boxed{72/36} = 2$$

$$E[g(X)] = \sum_i g(i) p(i) = \boxed{72/36} = 2$$

## expectation of a *function* of a random variable

Above example is not a fluke.

**Theorem:** if  $Y = g(X)$ , then  $E[Y] = \sum_i g(x_i)p(x_i)$ , where  $x_i, i = 1, 2, \dots$  are all possible values of  $X$ .

**Proof:** Let  $y_j, j = 1, 2, \dots$  be all possible values of  $Y$ .

Note that  $S_j = \{ x_i \mid g(x_i)=y_j \}$  is a partition of the domain of  $g$ .

$$\begin{aligned} \sum_i g(x_i)p(x_i) &= \sum_j \sum_{i:g(x_i)=y_j} g(x_i)p(x_i) \\ &= \sum_j \sum_{i:g(x_i)=y_j} y_j p(x_i) \\ &= \sum_j y_j \sum_{i:g(x_i)=y_j} p(x_i) \\ &= \sum_j y_j P\{g(X) = y_j\} \\ &= E[g(X)] \end{aligned}$$

## properties of expectation

A & B each bet \$1, then flip 2 coins:

HH	A wins \$2
HT	Each takes back \$1
TH	
TT	B wins \$2

Let  $X$  be A's net gain: +1, 0, -1, resp.:

$$P(X = +1) = 1/4$$

$$P(X = 0) = 1/2$$

$$P(X = -1) = 1/4$$

What is  $E[X]$ ?

$$E[X] = 1 \cdot 1/4 + 0 \cdot 1/2 + (-1) \cdot 1/4 = 0$$

What is  $E[X^2]$ ?

$$E[X^2] = 1^2 \cdot 1/4 + 0^2 \cdot 1/2 + (-1)^2 \cdot 1/4 = 1/2$$

Note:

$$E[X^2] \neq E[X]^2$$

### Linearity of expectation, I

For any constants  $a, b$ :  $E[aX + b] = aE[X] + b$

Proof:

$$\begin{aligned} E[aX + b] &= \sum_x (ax + b) \cdot p(x) \\ &= a \sum_x xp(x) + b \sum_x p(x) \\ &= aE[X] + b \end{aligned}$$

Example:

Q: In the 2-person coin game above, what is  $E[2X+1]$ ?

A:  $E[2X+1] = 2E[X]+1 = 2 \cdot 0 + 1 = 1$

## Linearity, II

Let  $X$  and  $Y$  be two random variables derived from outcomes of a single experiment. Then

$$E[X+Y] = E[X] + E[Y] \quad \text{True even if } X, Y \text{ dependent}$$

**Proof:** Assume the sample space  $S$  is countable. (The result is true without this assumption, but I won't prove it.) Let  $X(s)$ ,  $Y(s)$  be the values of these r.v.'s for outcome  $s \in S$ .

Claim:  $E[X] = \sum_{s \in S} X(s) \cdot p(s)$

**Proof:** similar to that for “expectation of a function of an r.v.,” i.e., the events “ $X=x$ ” partition  $S$ , so sum above can be rearranged to match the definition of  $E[X] = \sum_x x \cdot P(X = x)$

Then:

$$\begin{aligned} E[X+Y] &= \sum_{s \in S} (X[s] + Y[s]) p(s) \\ &= \sum_{s \in S} X[s] p(s) + \sum_{s \in S} Y[s] p(s) = E[X] + E[Y] \end{aligned}$$

### Example

$X = \#$  of heads in *one* coin flip, where  $P(X=1) = p$ .

What is  $E(X)$ ?

$$E[X] = 1 \cdot p + 0 \cdot (1-p) = p$$

Let  $X_i, 1 \leq i \leq n$ , be  $\#$  of H in flip of coin with  $P(X_i=1) = p_i$

What is the expected number of heads when all are flipped?

$$E[\sum_i X_i] = \sum_i E[X_i] = \sum_i p_i$$

Special case:  $p_1 = p_2 = \dots = p$  :

$$E[\# \text{ of heads in } n \text{ flips}] = pn$$

## Note:

Linearity is special!

It is *not* true in general that

$$E[X \cdot Y] = E[X] \cdot E[Y]$$

$$E[X^2] = E[X]^2$$

$$E[X/Y] = E[X] / E[Y]$$

$$E[\text{asinh}(X)] = \text{asinh}(E[X])$$

← counterexample above

-

## Application: The Probabilistic Method

---

Bunch of prisoners in a jail.

Two lunch slots: A and B.

R pairs of prisoners are risky.

Is there a way to assign the prisoners to lunch slots so that at least  $1/2$  the risky pairs are broken up (assigned to different lunch slots)?

$X$ : number of risky pairs that are broken up

$$E(X) = |R|/2.$$

$\implies$  there is an assignment of prisoners to lunch slots such that at least half of the risky pairs are broken up.

Cool! We showed it exists without finding it, using a probabilistic argument.

Alice & Bob are gambling (again).  $X$  = Alice's gain per flip:

$$X = \begin{cases} +1 & \text{if Heads} \\ -1 & \text{if Tails} \end{cases}$$

$$E[X] = 0$$

... Time passes ...

Alice (yawning) says "let's raise the stakes"

$$Y = \begin{cases} +1000 & \text{if Heads} \\ -1000 & \text{if Tails} \end{cases}$$

$E[Y] = 0$ , as before.

Are you (Bob) equally happy to play the new game?

$E[X]$  measures the “average” or “central tendency” of  $X$ .

What about its *variability*?

### Definition

The *variance* of a random variable  $X$  with mean  $E[X] = \mu$  is  $\text{Var}[X] = E[(X-\mu)^2]$ , often denoted  $\sigma^2$ .

Alice & Bob are gambling (again).  $X$  = Alice's gain per flip:

$$X = \begin{cases} +1 & \text{if Heads} \\ -1 & \text{if Tails} \end{cases}$$

$$E[X] = 0$$

$$\underline{\text{Var}[X] = 1}$$

... Time passes ...

Alice (yawning) says "let's raise the stakes"

$$Y = \begin{cases} +1000 & \text{if Heads} \\ -1000 & \text{if Tails} \end{cases}$$

$$E[Y] = 0, \text{ as before.}$$

$$\underline{\text{Var}[Y] = 1,000,000}$$

Are you (Bob) equally happy to play the new game?

$E[X]$  measures the “average” or “central tendency” of  $X$ .  
What about its *variability*?

### Definition

The *variance* of a random variable  $X$  with mean  $E[X] = \mu$  is  $\text{Var}[X] = E[(X-\mu)^2]$ , often denoted  $\sigma^2$ .

The *standard deviation* of  $X$  is  $\sigma = \sqrt{\text{Var}[X]}$

$\mu = E[X]$  is about *location*;  $\sigma = \sqrt{\text{Var}(X)}$  is about *spread*

Two games:

a) flip 1 coin, win  $Y = \$100$  if heads,  $-\$100$  if tails

b) flip 100 coins, win  $Z = (\#(\text{heads}) - \#(\text{tails}))$  dollars

Same expectation in both:  $E[Y] = E[Z] = 0$

Same extremes in both: max gain =  $\$100$ ; max loss =  $-\$100$

But  
variability  
is very  
different:
