Homework 8: Multiple RVs and Concentration

Version 2: We updated the number of balls in problem 4 so that the numbers are easier.

For each problem, remember you must briefly explain/justify how you obtained your answer, as correct answers without an explanation will not receive full credit. Moreover, in the event of an incorrect answer, we can still try to give you partial credit based on the explanation you provide.

In general, your goal in an explanation is to write enough that a student from class who has attended lecture, but not read the problem yet, could understand your approach, verify your reasoning, and believe your answer is correct. While we do not usually need to see arithmetic, you must include enough work that in principle one could rederive your answer with only a scientific calculator. For each problem, make sure to explicitly define all random variables you use, and be clear about how they are related to each other using proper notation (conditionals, summations, etc.).

Unless a problem states otherwise, you should leave your answer in terms of factorials, combinations, etc., for instance $26^7$ or $26! / 7!$ or $26 \cdot \binom{26}{7}$ are all good forms for final answers.

Instructions as to how to upload your solutions to gradescope are on the course web page.

Remember that you must tag your written problems on Gradescope.

Submission: You must upload a pdf of your written solutions to Gradescope under “HW 8”. (Instructions as to how to upload your solutions to gradescope are on the course web page.) The use of latex is highly recommended. (Note that if you want to hand-write your solutions, you'll need to scan them. We will take off points for hand-written solutions that are difficult to read due to poor handwriting and neatness.)

Due Date: This assignment is due at 11:59 PM Wednesday May 26 (Seattle time, i.e. GMT-7). You will submit the written problems as a PDF to gradescope. Please put each numbered problem on its own page of the pdf (this will make selecting pages easier when you submit), and ensure that your pdfs are oriented correctly (e.g. not upside-down or sideways). The coding problem will also be submitted to gradescope.

Collaboration: Please read the full collaboration policy. If you work with others (and you should!), you must still write up your solution independently and name all of your collaborators somewhere on your assignment.

For calculations that require evaluating integrals (unless we indicate otherwise), you must

(a) Show the integral to evaluate (e.g., $\int_0^2 z \cdot 2dz$)

(b) Show an antiderivative and the values to evaluate at (e.g., $z^2|_0^2$)

(c) Plug in the values and simplify (e.g., $2^2 - 0^2 = 4$)

1. Statistics Books [24 points]

Alice is going shopping for statistics books for $H$ hours, where $H$ is a random variable, equally likely to be 1, 2 or 3. The number of books $B$ she buys is random and depends on how long she is in the store for. We are told that

\[ \Pr(B = b|H = h) = \frac{c}{h}, \quad \text{for } b = 1, \ldots, h, \]

for some constant $c$.

(a) Compute $c$. You may want to use one of the axioms of probability.

(b) Find the joint distribution of $B$ and $H$ using the chain rule.

(c) Find the marginal distribution of $B$.

(d) Find the conditional distribution of $H$ given that $B = 1$ (i.e., $\Pr(H = h|B = 1)$ for each possible $h$ in 1,2,3). Use the definition of conditional probability and the results from previous parts.
(e) Suppose that we are told that Alice bought either 1 or 2 books. Find the expected number of hours she shopped conditioned on this event. Use the law of total expectation and conditional probability theorems.

(f) The cost of each book is a random variable with mean 3, and is independent of the number of books Alice buys. What is the expected amount of money Alice spends? **Warning**: you might be tempted to skip some steps and assert that expected amount of money spent is 3 times the expected cost of each book. Even though the answer is intuitive, its formal derivation is a lot more involved. We expect you to show each step you used to get to that expression. Your work should involve the law of total expectation conditioning on the number of books bought, and make use of indicator random variables.

2. **Coal Mining [24 points]**

A miner is trapped in a mine containing 4 doors, and each door is equally likely to be chosen. The first door leads to a tunnel that will take him to safety after a number of hours which is Poisson with parameter 2. The second door leads to a tunnel that will take him to safety after a number of hours which is Geometric with parameter \( \frac{1}{5} \). The third door leads to a tunnel that will take him to safety after a number of hours which is binomial with parameters \( n = 100 \) and \( p = \frac{1}{20} \). The fourth door leads to a tunnel which brings him back to where he started after 2 hours. Use the law of total expectation to compute the expected number of hours until the miner reaches safety.

3. **Knitting Requires Concentration [16 points]**

Robbie is slowly knitting a blanket, made of 100 squares. It takes an average of 1 hour for Robbie to knit a square, with a variance of 0.1 hours. The time to knit each square is independent.

You should treat time as continuous for this problem.

(a) What is the expectation of the total time to knit the blanket? [2 points]

(b) What is the variance of the total time to knit the blanket? [2 points]

(c) Robbie will have 85 hours to knit between now and when he needs the blanket to be finished to stay warm at a football game. Use Markov’s Inequality to bound the probability that Robbie finishes the blanket before the game. Hint: you’ll need to take a complement. [6 points]

(d) Robbie will have 115 hours to knit between now and the start of basketball season (total, including the 85 hours before the cold football game). Use Chebyshev’s inequality to bound the probability that Robbie finishes the blanket after the football game, but in time for basketball season. [6 points]

4. **Urns [21 points]**

You have 2500 urns, that you place into a 50-by-50 grid. You will throw 40,000 balls (independently) toward the grid of urns, with equal probability for the ball to go in each urn.

You hope that at the end of the process, each urn will have at least 4 balls inside. You want to upperbound the probability that you will fail to get at least 4 balls into every urn.

(a) Use a Chernoff bound from class to bound the probability that the urn in the lower-left of the grid does not have at least 4 balls inside. [10 points]

(b) Is the probability of the lower-left urn having less than 4 balls independent of the probability that the urn in the upper-right has less than 4 balls? Briefly explain (you may give a formal derivation/calculation as an explanation or an informal one). [3 points]
(c) Bound the probability that any urn has fewer than 4 balls. Give the best bound you can from your answers in (a) and (b). [8 points]
