Problem Set 4
Due: Wednesday, April 27, by 11:59pm

Instructions

Solutions format, collaboration policy, and late policy. See PSet 1 for further details. The same requirements and policies still apply. Also follow the typesetting instructions from the prior PSets.

Solutions submission. You must submit your solution via Gradescope. In particular:

- For the solutions to Task 1-6, and the written part of Task 7, submit under “PSet 4 [Written]” a single PDF file containing the solution to all tasks in the homework. Each numbered task should be solved on its own page (or pages). Follow the prompt on Gradescope to link tasks to your pages. Do not write your name on the individual pages – Gradescope will handle that.

- For the programming part (part of Task 7), submit your code under “PSet 4 [Coding]” as a file called bloom.py.

- For the extra credit Task (Task 8), submit a separate PDF file under “PSet 4 [Optional]”.

Task 1 – Fair Game [10 pts]
Consider the following game, defined by a parameter $k$: Roll a fair, 6-sided die three times independently. If you roll a six
- no times, then you lose 1 dollar.
- exactly once, you win 1 dollar.
- exactly twice, then you win 2 dollars.
- all three times, then you win $k$ dollars.

For what value of $k$ is this game fair? (The game is fair if your expected payoff is 0.)

Task 2 – Raining Cats and Dogs [12 pts]
Suppose that $4n$ animals are partitioned into pairs at random, with each partition being equally likely. If the set consists of $n$ dogs and $3n$ cats, what is the expected number of dog-cat pairs?

Task 3 – Tournament Prediction Games [14 pts]
A well-known college sports tournament starts with 64 teams and eliminates half of the teams in each round of games. There are 32 1st-round games, 16 2nd-round games, ..., and 1 6th-round game. The teams are scheduled to play each other according to a fixed full binary tree of height 6. Each team begins at one of the leaves of the tree and plays the team at the sibling node. The winner moves up to the parent node and this repeats until there is one overall champion left at the root.

You have a chance to play a game where you try to predict the winner of every one of the 63 games. You know the assignment of teams to the leaves of the tree. If you predict an $i$-th round game correctly, you get a payoff of $2^{i-1}$. That is, for a 1st round game you get a payoff of 1, for a 2nd round game you get a payoff of 2, ..., and you get a payoff of 32 if you predict the winner of the 6th round final game.
a) Suppose that you predicted the game corresponding to each internal node of the tree by choosing a uniformly random team from the teams at the leaves in the subtree for that node – ignoring what you predicted for the nodes lower in the tree. (There are $2^i$ teams in the subtree if the game is in round $i$.) What would your total expected payoff be?

b) Suppose instead that you started at the leaves and predicted the winner of each game by flipping a separate independent fair coin for each node to select the winner of the game corresponding to that node from the two winners you predicted for the games corresponding to its two child nodes. What is your total expected payoff now?

**Task 4 – Independence**

We are given two independent random variables, $M$ and $K$, both taking values in $\{0, 1, 2, 3, 4, 5\}$. Further, assume that you know that the marginal distribution of $K$ is uniform, i.e., $P[K = i] = 1/6$ for all $i \in \{0, 1, 2, \ldots, 5\}$. You do not know the marginal distribution of $M$. Finally, we define a new random variable $C$ as

$$C = (M + K) \mod 6.$$

a) For every $m, c \in \{0, 1, \ldots, 5\}$, what is the probability $P[C = c, M = m]$ as a function of $P[M = m]$?

b) For every $c \in \{0, 1, \ldots, 5\}$, what is $P[C = c]$?

c) Show that $M$ and $C$ are (mutually) independent.

**Task 5 – Some Really Odd Dice!**

You are playing a game that uses a fair 8-sided die whose faces are numbered by the odd numbers, 1, 3, 5, . . . , 15. The value of a roll is the number showing on the top of the die when it comes to rest. Give all answers as simplified fractions.

a) Let $X$ be the value of one roll of the die. Compute $\mathbb{E}[X]$ and $\text{Var}(X)$.

b) Let $Y$ be the sum of the values of 5 independent rolls of the die. Compute $\mathbb{E}[Y]$ and $\text{Var}(Y)$. Use independence, and state precisely where in your computation you are using it.

c) Let $Z$ be the average of the values of $n$ independent rolls of the die. Compute $\mathbb{E}[Z]$ and $\text{Var}(Z)$. Use independence, and state precisely where in your computation you are using it.

**Task 6 – Packet Failures**

Consider three different models for sending $n$ packets over the Internet:

1. Each packet takes a different path. Each path fails independently with probability $p$;

2. All packets take the exact same path which fails with probability $p$. Thus, either all the packets get through or none get through;

3. Half the packets take one path, and half take the other (assume $n$ is even), and each of the two paths fails independently with probability $p$.

Let $X_i$ be the number of packets lost in case $i$, for $i = 1, 2, 3$. Write down the probability mass function, the expectation of $X_i$, and the variance of $X_i$ for $i = 1, 2, 3$. 

---

2
Task 7 – Bloom filters [Coding+Written] [10+8 pts]

Google Chrome has a huge database of malicious URLs, but it takes a long time to do a database lookup (think of this as a typical Set). They want to have a quick check in the web browser itself, so a space-efficient data structure must be used. A **Bloom filter** is a probabilistic data structure which only supports the following two operations:

- **add(x)**: Add an element x to the structure.
- **contains(x)**: Check if an element x is in the structure. If either returns “definitely not in the set” or “could be in the set”.

It does not support the following two operations:

- delete an element from the structure.
- return an element that is in the structure.

The idea is that we can check our Bloom filter to see if a URL is in the set. The Bloom filter is always correct in saying a URL definitely isn’t in the set, but may have false positives – it may say that a URL is in the set when it isn’t. Only in these rare cases does Chrome have to perform an expensive database lookup to know for sure.

Suppose that we have k bit arrays t_1, . . . , t_k each of length m (all entries are 0 or 1), so the total space required is only km bits or km/8 bytes (as a byte is 8 bits). Suppose that the universe of URL’s is the set U (think of this as all strings with less than 100 characters), and we have k independent and uniform hash functions h_1, . . . , h_k : U → {0, 1, . . . , m − 1}. That is, for an element x and hash function h_i, pretend h_i(x) is a discrete Unif(0, m − 1) random variable. Suppose that we implement the add and contains function as follows:

**Algorithm 1 Bloom Filter Operations**

1: function INITIALIZE(k,m)
2:     for i = 1, . . . , k: do
3:     t_i = new bit array of m 0’s
4: function ADD(x)
5:     for i = 1, . . . , k: do
6:     t_i[h_i(x)] = 1
7: function CONTAINS(x)
     return t_1[h_1(x)] == 1 ∧ t_2[h_2(x)] == 1 ∧ · · · ∧ t_k[h_k(x)] == 1

Refer to the slides from Lecture 11 and Section 9.4 of the textbook for more details on Bloom filters.

**a)** Implement the functions add and contains in the BloomFilter class of bloom.py.

To solve this task, we have set up a corresponding edstem lesson here. Press the Mark button above the terminal to run the unit tests we have written for you. Passing these unit tests is not enough. We have written a number of different tests for the Gradescope autograder. Your score on Gradescope will be your actual score - you have unlimited attempts to submit.

**b)** Let’s compare this approach to using a typical Set data structure. Google wants to store 1 million URLs, with each URL taking (on average) 25 bytes. How much space (in MB, 1 MB = 1 million bytes) is required if we store all the elements in a set? How much space (in MB) is required if we store all the elements in a Bloom filter with k = 10 hash functions and m = 800,000 buckets? Recall that 1 byte = 8 bits.

**c)** Let’s analyze the time improvement as well. Let’s say an average Chrome user attempts to visit 51,000 URLs in a year, only 1,000 of which are actually malicious. Suppose it takes half a second for Chrome to make a call to the database (the Set), and only 1 millisecond for Chrome to check containment in the Bloom filter. Suppose the false positive rate on the Bloom filter is 4%; that is, if a website is not malicious, the Bloom
filter will incorrectly report it as malicious with probability 0.04. What is the time (in seconds) taken if we only use the database, and what is the expected time taken (in seconds) to check all 51,000 strings if we used the Bloom filter + database combination described earlier?

**Task 8 – Extra Credit Problem**

You are shown two envelopes and told the following facts:

- Each envelope has some number of dollars in it, but you don’t know how many.
- The amount in the first envelope is different from the amount in the second.
- Although you don’t know exactly how much money is in each envelope, you are told that it is an integer number of dollars that is at least 1 and at most 100.
- You are told that you can pick an envelope, look inside, and then you will be given a one-time option to switch envelopes (without looking inside the new envelope). You will then be allowed to keep the money in envelope you end up with.

Your strategy is the following:

1. You pick an envelope uniformly at random.
2. You open it and count the amount of money inside. Say the result is $x$.
3. You then select an integer $y$ between 1 and 100 uniformly at random.
4. If $y > x$, you switch envelopes, otherwise you stay with the envelope you picked in step (a)

Show that you have a better than 50-50 chance of taking home the envelope with the larger amount of money in it. More specifically, suppose the two envelopes have $i$ and $j$ dollars in them respectively, where $i < j$. Calculate the probability that you take home the envelope with the larger amount of money.
