

## Quiz Section 9.5 – Solutions

### Review

1) A **discrete-time stochastic process (DTSP)** is a sequence of random variables  $X^{(0)}, X^{(1)}, X^{(2)}, \dots$ , where  $X^{(t)}$  is the value at time  $t$ . For example, the temperature in Seattle or stock price of TESLA each day, or which node you are at after each time step on a random walk on a graph.

2) **Markov Chain** is a DTSP, with the additional following three properties:

(a) ...has a finite (or countably infinite) **state space**  $\mathcal{S} = \{s_1, \dots, s_n\}$  which it bounces between, so each  $X^{(t)} \in \mathcal{S}$ .

(b) ...satisfies the **Markov property**. A DTSP satisfies the Markov property if the future is (conditionally) independent of the past given the present. Mathematically, it means,

$$\mathbb{P}\left(X^{(t+1)} = x_{t+1} \mid X^{(0)} = x_0, X^{(1)} = x_1, \dots, X^{(t-1)} = x_{t-1}, X^{(t)} = x_t\right) = \mathbb{P}\left(X^{(t+1)} = x_{t+1} \mid X^{(t)} = x_t\right).$$

(c) ...has **fixed transition probabilities**. Meaning, if we are at some state  $s_i$ , we transition to another state  $s_j$  with probability *independent* of the current time. Due to this property and the previous, the transitions are governed by  $n^2$  probabilities: the probability of transitioning from one of  $n$  current states to one of  $n$  next states. These are stored in a square  $n \times n$  **transition probability matrix (TPM) M**, where  $M_{ij} = \mathbb{P}(X^{(t+1)} = s_j \mid X^{(t)} = s_i)$  is the probability of transitioning from state  $s_i$  to state  $s_j$  for any/every value of  $t$ .

3) A **stationary distribution** of a Markov chain is a probability distribution on states that is unchanged by taking one step of the Markov chain.

### Task 1 – Faulty Machines

You are trying to use a machine that only works on some days. If on a given day, the machine is working it will break down the next day with probability  $0 < b < 1$ , and works on the next day with probability  $1 - b$ . If it is not working on a given day, it will work on the next day with probability  $0 < r < 1$  and not work the next day with probability  $1 - r$ .

a) In this problem we will formulate this process as a Markov chain. First, let  $X^{(t)}$  be a variable that denotes the state of the machine at time  $t$ . Then, define a state space  $\mathcal{S}$  that includes all the possible states that the machine can be in. Lastly, for all  $A, B \in \mathcal{S}$  find  $\mathbb{P}(X^{(t+1)} = A \mid X^{(t)} = B)$  ( $A$  and  $B$  can be the same state).

Formally, a Markov chain is defined by a state space  $\mathcal{S}$  and a transition probability matrix. The two possible states of the machine are “working” and “broken”. So,  $\mathcal{S} = \{W, B\}$ . Let  $X_t$  be the state of the process at time  $t$ . Then we can define the following transition probabilities:

$$\mathbb{P}(X^{(t+1)} = W \mid X^{(t)} = W) = 1 - b \quad \mathbb{P}(X^{(t+1)} = B \mid X^{(t)} = W) = b$$

$$\mathbb{P}(X^{(t+1)} = W \mid X^{(t)} = B) = r \quad \mathbb{P}(X^{(t+1)} = B \mid X^{(t)} = B) = 1 - r$$

We can also represent the transition probabilities with the following matrix:

$$M = \begin{bmatrix} 1 - b & b \\ r & 1 - r \end{bmatrix}$$

where the  $ij$ -th entry is probability that the machine is in the  $j$ -th state at time  $t + 1$  given it was in state  $i$  at time  $t$ . (Here state 1 is working and state 2 is broken.)

b) Suppose that on day 1, the machine is working. What is the probability that it is working on day 3?

We are trying to find  $\mathbb{P}(X^{(3)} = W \mid X^{(1)} = W)$ . From the law of total probability, and then plugging in the values from our transition matrix:

$$\begin{aligned} \mathbb{P}(X^{(3)} = W \mid X^{(1)} = W) &= \sum_{i \in \mathcal{S}} \mathbb{P}(X^{(3)} = W \mid X^{(1)} = W, X^{(2)} = i) \cdot \mathbb{P}(X^{(2)} = i \mid X^{(1)} = W) \\ &= \mathbb{P}(X^{(3)} = W \mid X^{(2)} = W) \cdot \mathbb{P}(X^{(2)} = W \mid X^{(1)} = W) \\ &\quad + \mathbb{P}(X^{(3)} = W \mid X^{(2)} = B) \cdot \mathbb{P}(X^{(2)} = B \mid X^{(1)} = W) \\ &= \mathbb{P}(X^{(3)} = W \mid X^{(2)} = W) \cdot (1 - b) + \mathbb{P}(X^{(3)} = W \mid X^{(2)} = B) \cdot b \\ &= (1 - b)(1 - b) + rb \\ &= (1 - b)^2 + rb \end{aligned}$$

Alternative solution using matrix operations: Let  $q^{(t)}$  be the probability vector at time  $t$  associated with this Markov chain. The assumption that the machine is working on day 1 is the same as saying that the probability vector  $q^{(1)} = [1, 0]$ . Then

$$q^{(2)} = q^{(1)} \cdot M = [1 \ 0] \begin{bmatrix} 1 - b & b \\ r & 1 - r \end{bmatrix} = [1 - b \ b].$$

The probability we want to compute is the 1st entry of

$$q^{(3)} = q^{(2)} \cdot M = [1 - b \ b] \begin{bmatrix} 1 - b & b \\ r & 1 - r \end{bmatrix}$$

which equals  $(1 - b) \cdot (1 - b) + b \cdot r = (1 - b)^2 + br$ .

c) As  $n \rightarrow \infty$ , what does the probability that the machine is working on day  $n$  converge to? To get the answer, solve for the *stationary distribution*.

The stationary distribution is the row vector  $\pi = [\pi_W \ \pi_B]$  such that  $\pi P = \pi$ . The entries in the vector  $\pi_W$  and  $\pi_B$  can be interpreted as the probabilities that the machine works or is broken converge to. As such,  $\pi_W + \pi_B = 1$ . Additionally, multiplying the stationary distribution by the TPM gives us the following two equations (one per column of  $M$ ):

$$\pi_W = \pi_W(1 - b) + \pi_B r \quad \pi_B = \pi_W b + \pi_B(1 - r)$$

Solving these 3 equations for  $\pi_W$  and  $\pi_B$  gives us the following solutions for the stationary distribution:

$$\pi_W = \frac{r}{b + r} \quad \pi_B = \frac{b}{b + r}$$

So, as  $n \rightarrow \infty$  the probability that the machine works on day  $n$  is  $\pi_W = \frac{r}{b+r}$

## Task 2 – Another Markov Chain

Suppose that the following is the transition probability matrix for a 4 state Markov chain (states 1,2,3,4).

$$M = \begin{bmatrix} 0 & 1/2 & 1/2 & 0 \\ 1/3 & 0 & 0 & 2/3 \\ 1/3 & 1/3 & 0 & 1/3 \\ 1/5 & 2/5 & 2/5 & 0 \end{bmatrix}$$

a) What is the probability that  $X^{(2)} = 4$  given that  $X^{(0)} = 4$ ?

Let's denote the state space  $\mathcal{S} = \{1, 2, 3, 4\}$ . Using the law of total probability we can determine that

$$\begin{aligned} \mathbb{P}(X^{(2)} = 4 \mid X^{(0)} = 4) &= \sum_{i \in \mathcal{S}} \mathbb{P}(X^{(2)} = 4 \mid X^{(0)} = 4, X^{(1)} = i) \mathbb{P}(X^{(1)} = i \mid X^{(0)} = 4) \\ &= \sum_{i \in \mathcal{S}} \mathbb{P}(X^{(2)} = 4 \mid X^{(1)} = i) \mathbb{P}(X^{(1)} = i \mid X^{(0)} = 4) \\ &= 0 + \frac{2}{5} \cdot \frac{2}{3} + \frac{2}{5} \cdot \frac{1}{3} + 0 \\ &= \frac{2}{5} \end{aligned}$$

Alternative solution using matrix operations: Let  $q^{(t)}$  be the probability vector at time  $t$  associated with this Markov chain. The statement that  $X^{(0)} = 4$  is equivalent to saying that the probability vector  $q^{(0)} = [0, 0, 0, 1]$ . Therefore

$$q^{(1)} = q^{(0)} \cdot M = [0 \ 0 \ 0 \ 1] \cdot \begin{bmatrix} 0 & 1/2 & 1/2 & 0 \\ 1/3 & 0 & 0 & 2/3 \\ 1/3 & 1/3 & 0 & 1/3 \\ 1/5 & 2/5 & 2/5 & 0 \end{bmatrix} = [1/5 \ 2/5 \ 2/5 \ 0].$$

What we want is the 4-th entry of

$$q^{(2)} = q^{(1)} \cdot M = [1/5 \ 2/5 \ 2/5 \ 0] \cdot \begin{bmatrix} 0 & 1/2 & 1/2 & 0 \\ 1/3 & 0 & 0 & 2/3 \\ 1/3 & 1/3 & 0 & 1/3 \\ 1/5 & 2/5 & 2/5 & 0 \end{bmatrix}$$

This is  $0 + \frac{2}{5} \cdot \frac{2}{3} + \frac{2}{5} \cdot \frac{1}{3} + 0 = 2/5$ .

b) Write down the system of equations that the stationary distribution must satisfy and solve them.

The stationary distribution is the row vector  $\pi = [\pi_1 \ \pi_2 \ \pi_3 \ \pi_4]$  such that  $\pi P = \pi$ . We know that  $\pi_1 + \pi_2 + \pi_3 + \pi_4 = 1$ . Additionally, multiplying the stationary distribution by the TPM gives us the following equations:

$$\begin{aligned} \pi_1 &= \frac{1}{3}\pi_2 + \frac{1}{3}\pi_3 + \frac{1}{5}\pi_4 \\ \pi_2 &= \frac{1}{2}\pi_1 + \frac{1}{3}\pi_3 + \frac{2}{5}\pi_4 \\ \pi_3 &= \frac{1}{2}\pi_1 + \frac{2}{5}\pi_4 \\ \pi_4 &= \frac{2}{3}\pi_2 + \frac{1}{3}\pi_3 \end{aligned}$$

Solving these 5 equations for each  $\pi_i$  gives us the following solutions for the stationary distribution:

$$\pi_1 = \frac{46}{206} \quad \pi_2 = \frac{60}{206} \quad \pi_3 = \frac{45}{206} \quad \pi_4 = \frac{55}{206}$$

### Task 3 – Three Tails

You flip a fair coin until you see three tails in a row. Model this as a Markov chain with the following states:

- $S$ : start state, which we are only in before flipping any coins.
- $H$ : We see a heads, which means no streak of tails currently exists.
- $T$ : We've seen exactly one tail in a row so far.
- $TT$ : We've seen exactly two tails in a row so far.
- $TTT$ : We've accomplished our goal of seeing three tails in a row, stop flipping, and stay there.

a) Write down the transition probability matrix.

$$M = \begin{bmatrix} 0 & 1/2 & 1/2 & 0 & 0 \\ 0 & 1/2 & 1/2 & 0 & 0 \\ 0 & 1/2 & 0 & 1/2 & 0 \\ 0 & 1/2 & 0 & 0 & 1/2 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

b) Write down the system of equations whose variables are  $D(s)$  for each state  $s \in \{S, H, T, TT, TTT\}$ , where  $D(s)$  is the expected number of steps until state  $TTT$  is reached starting from state  $s$ . Solve this system of equations to find  $D(S)$ .

Using the law of total expectation and the transition probability matrix above we can set up and solve the following system of equations:

$$\begin{aligned} D(TTT) &= 0 \\ D(TT) &= 1 + \frac{1}{2}D(H) + \frac{1}{2}D(TTT) = \frac{1}{2}D(H) + 1 \\ D(T) &= 1 + \frac{1}{2}D(H) + \frac{1}{2}D(TT) = \frac{3}{4}D(H) + \frac{3}{2} \\ D(H) &= 1 + \frac{1}{2}D(H) + \frac{1}{2}D(T) = \frac{7}{8}D(H) + \frac{7}{4} \\ D(S) &= 1 + \frac{1}{2}D(H) + \frac{1}{2}D(T) = \frac{7}{8}D(H) + \frac{7}{4} \end{aligned}$$

Solving for  $D(H)$  gives us that  $D(H) = 14$ , which allows us to solve for the rest of the expected number of steps,  $D(TT) = 8$ ,  $D(T) = 12$ ,  $D(S) = 14$ . So, we expect to flip 14 coins before we flip three tails in a row.

c) Write down the system of equations whose variables are  $\gamma(s)$  for each state  $s \in \{S, H, T, TT, TTT\}$ , where  $\gamma(s)$  is the expected number of heads seen before state  $TTT$  is reached. Solve this system to find  $\gamma(S)$ , the expected number of heads seen overall until getting three tails in a row.

Like in the previous part we can use the LoTE and the Transition Probability Matrix to set up and solve the following system of equations. We get one equation for each column of  $M$ :

$$\begin{aligned} \gamma(TTT) &= 0 \\ \gamma(TT) &= 0.5\gamma(H) + 0.5\gamma(TTT) = 0.5\gamma(H) \\ \gamma(T) &= 0.5\gamma(H) + 0.5\gamma(TT) = 0.75\gamma(H) \\ \gamma(H) &= 1 + 0.5\gamma(H) + 0.5\gamma(T) = 0.875\gamma(H) + 1 \\ \gamma(S) &= 0.5\gamma(H) + 0.5\gamma(T) = 0.875\gamma(H) \end{aligned}$$

Solving for  $\gamma(H)$  gives us  $\gamma(H) = 8$ . This allows us to solve for the other expected values which are  $\gamma(TT) = 4$ ,  $\gamma(T) = 6$ ,  $\gamma(S) = 7$ . So, we expect to see 7 heads before we flip three tails in a row.
