## CSE 312: Foundations of Computing II Practice Final Exam

## **Instructions:**

- Give your answers in the spaces provided on these sheets.
- Give a brief justification for each answer. Usually it is sufficient just to show the formula you are using and then substitute into the formula according to the problem details. Don't forget to define any events or random variables that you use, so that we know what your variables represent.
- If you continue an answer on the back of a page, be sure to indicate that on the front of the page.
- No calculators or other electronic devices allowed.

## Reference Sheet

- 1. Formulas related to permutations and combinations.
  - $\bullet \binom{n}{k} = \frac{n!}{k! \cdot (n-k)!}.$
  - Binomial identity:  $(x+y)^n = \binom{n}{0}x^n + \binom{n}{1}x^ny + \ldots + \binom{n}{n}y^n$ .
- 2. Inclusion exclusion principle:

$$|A_1 \cup A_2 \cup \cdots \cup A_n| = |A_1| + \cdots + |A_n| - |A_1 \cap A_2| - \cdots - |A_{n-1} \cap A_n| + \cdots$$

- 3. Bayes' rule:  $\mathbb{P}(A \mid B) = \frac{\mathbb{P}(B|A) \cdot \mathbb{P}(A)}{\mathbb{P}(B)}$ .
- 4. Chernoff-Hoeffding bound: If X is sum of independent Bernoulli's with mean  $\mu$ , then

$$\mathbb{P}(|X - \mu| > \delta\mu) \le 2e^{\delta^2\mu/(2+\delta)}.$$

5. Some standard discrete distributions:

distribution	${f probability}$	expectation	variance
Bernoulli	$\mathbb{P}(x=1) = p, \mathbb{P}(x=0) = 1 - p$	p	$p-p^2$
Binomial	$\mathbb{P}(X=k) = \binom{n}{k} p^k (1-p)^{n-k}$	pn	$(p-p^2)n$
Geometric	$\mathbb{P}\left(X=k\right) = p(1-p)^{k-1}$	1/p	$\frac{1-p}{p^2}$
Poisson	$\mathbb{P}(X = k) = e^{-\lambda} \cdot \frac{\lambda^k}{k!}$	$\lambda$	$\lambda$

6. Some standard continuous distributions are shown below. Here  $\Phi(x)$  is the cdf of the standard normal.

distribution	$\operatorname{pdf}$	$\operatorname{cdf}$	expectation	variance	mgf
Normal	$\frac{1}{\sqrt{2\pi}\sigma} \cdot e^{-\frac{(x-\mu)^2}{2\sigma^2}}$	$\Phi((x-\mu)/\sigma)$	$\mu$	$\sigma^2$	$e^{t\mu} \cdot e^{t^2\sigma^2/2}$
Exponential	$\lambda e^{-\lambda t}$	$1 - e^{-\lambda t}$	$1/\lambda$	$1/\lambda^2$	$_{\rm n/a}$

- 1. For each of the following assertions:
  - (3 points) State whether they are True or False.
  - (2 points) Briefly justify your answer.
  - (a) The number of distinct rearrangements of the letters of the word BALLOON in which B and N occur together is  $\frac{6!}{2!2!}$ .
  - (b) Let A and B be events in the same sample space. If  $\mathbb{P}(A|B) = 1/2$ , then  $\mathbb{P}(A|B^c) = 1/2$ .
  - (c) 50% of all rainy days start off cloudy. However, 40% of days start cloudy. If only 10% of the days are rainy, then the chance of rain during the day given that the morning is cloudy is 12.5%.
  - (d) If X is a random variable taking on non-negative integer values, and for each integer k, let  $E_k$  be the event that X = k. Then the set of events  $E_0, E_1, \ldots$  form a partition of the probability space.
  - (e) Suppose  $X_1, \ldots, X_k$  are pairwise independent real valued random variables. Then  $\operatorname{Var}(X_1 + \ldots + X_k) = \operatorname{Var}(X_1) + \ldots + \operatorname{Var}(X_k)$ .
  - (f) Let  $X \in \{1, 2, 3, 4\}$  be uniformly random and Y be independent and uniformly random in  $\{1, 2, 3, 4, 5\}$ . Then  $\mathbb{P}(X = Y) = 1/5$ .

- (g) If X has a Poisson distribution with parameter 3, then 2X has Poisson distribution with parameter 6.
- (h) Let X be a real random variable with PDF f. Then the PDF of 2X is given by  $\int_{-\infty}^{\infty} f(x')f(x-x')dx'$ .
- (i) We have n balls and n bins. Each ball is thrown into a uniform random bin and each throw is independent of the other. Let  $X_i$  be 1 if the i'th bin is non-empty and 0 otherwise. Define  $X = X_1 + \ldots + X_n$ . We can now apply Chernoff's bound to say

$$\mathbb{P}\left(\left|X - \mathbb{E}\left(X\right)\right| \ge \delta \mathbb{E}\left(X\right)\right) \le 2e^{-\frac{\delta^{2}\mathbb{E}\left(X\right)}{2+\delta}}.$$

- (j) Let X and Y be random variables. If  $\mathbb{E}(XY) = \mathbb{E}(X)\mathbb{E}(Y)$ , then X and Y are not independent.
- (k) Let X and Y be non-negative random variables. Then for every a > 0,

$$\mathbb{P}\left(X + Y \ge a\right) \le \frac{\mathbb{E}\left(X\right) + \mathbb{E}\left(Y\right)}{a}.$$

- (l) If X is a random variable with  $\mathbb{E}\left(e^{tX}\right)=e^{2t^2}$ , then X must have a normal distribution.
- (m) Let X be a real random variable with CDF F. Then if a < b, we must have

$$F(a) < F(b)$$
.

(n) Suppose we are given two distributions on real numbers. For each n, suppose  $X_1, X_2, \ldots, X_n, Y_1, \ldots, Y_n$  are independent random variables, with  $X_i$  sampled according to the first distribution, and  $Y_i$  sampled according to the second distribution, for all i. Suppose the mean and standard deviations of the first distribution are  $\mu_1, \sigma_1$ , and the corresponding parameters for the second distribution are  $\mu_2, \sigma_2$ . Then for every number  $\alpha$ , the limit

$$\lim_{n \to \infty} p\left(\frac{X_1 + X_2 + \ldots + X_n + Y_1 + \ldots + Y_n - n(\mu_1 + \mu_2)}{\sqrt{n(\sigma_1^2 + \sigma_2^2)}} < \alpha\right) = \Phi(\alpha),$$

where  $\Phi$  is the cdf of the standard normal.

- 2. You want to get rich quickly, so you buy 10,000 lottery tickets for \$1 each. Each ticket has probability  $10^{-6}$  of winning \$6000, independently of the other tickets. Let random variable X be the number of winning lottery tickets among your 10,000.
  - (a) (10 points) What is the probability that X = k?

(b) (10 points) Give the parameters for the Poisson random variable Y that approximates X well, and use the Poisson approximation to write a formula that should estimate the probability that you make a net profit with your 10,000 tickets.

3.	The time it takes to write a piece of software is modeled as a continuous random
	variable $X$ from an unknown distribution. You would like to be able to guarantee a
	client that, with high probability, the software will be completed within 48 days. What
	is the best guarantee you could give under each of the following conditions? Justify
	your answer.

(a)	(6 points)	You	know	that	X	has	mean	20.	Give	an	${\rm exact}$	answer	as	a sir	nplified
	fraction.														

(b) (6 points) You know that X has mean 20 and variance 100. Give an exact answer as a simplified fraction.

(c) (8 points) You know that X is well approximated by the normal with mean 20 and standard deviation 100. Give your answer in terms of the cdf of the standard normal,  $\Phi(x)$ .

4.	You are playing a slot machine for which you must insert \$1 per play. It pays you back
	\$10 with probability 0.02, pays \$5 with probability 0.1, and pays nothing otherwise.
	Let the random variable $X$ be your net gain in dollars on a single play. (Net gain
	includes the \$1 you pay to play. For example, if the machine pays you back \$10, your
	net gain is \$9.)

(a) (5 points) Compute E[X] exactly, with no rounding.

(b) (7 points) Compute Var(X) exactly, with no rounding.

(c) (8 points) Let Y be your total net gain in 20 independent plays of this slot machine. Use the Central Limit Theorem to estimate the probability that you make a profit. Express your answer in terms of the cdf of the standard normal.

5. You are in a disreputable casino, where you suspect they use a loaded 6-sided die. This loaded die rolls a 1 with probability  $3\theta$  (and rolls 2 with the same probability), rolls a 3 with probability  $2\theta$  (and rolls 4 with the same probability), and rolls a 5 with probability  $\frac{1}{2} - 5\theta$  (and rolls 6 with the same probability), where  $0 < \theta < 0.1$  is unknown. In order for you to beat the casino, it will help if you can estimate the value of  $\theta$ . To do this, you record the outcomes of several independent rolls of the die as follows:

outcome	1	2	3	4	5	6
frequency	6	4	2	6	2	3

Find the maximum likelihood estimator  $\hat{\theta}$  of  $\theta$ . Show how to derive  $\hat{\theta}$ , and don't forget to show that it is a maximum.

(Hint to save you work: you will get the correct answer to this part even if you make the simplifying assumption that the first 6 rolls are 1, the next 4 rolls are 2, etc. Without this assumption, your likelihood function would have some complicated multinomial coefficient, but that factor has no dependence on  $\theta$  so you can ignore it.)
