Lecture 09: Structural Induction

# Structural Induction

- Show  $P$  holds for all basis elements of  $S$ .
- Show that  $P$  holds for elements used to construct a new element of  $S$ , then  $P$  holds for the new elements.

Prove all elements of  $S$  are divisible  
by 3

- Basis:  $6 \in S$ ;  $15 \in S$ ;
- Recursive: if  $x, y \in S$ , then  $x + y \in S$ ;

# Structural Induction

Let  $\Sigma = \{a, b\}$ ; think of  $a = "("$  and  $b = ")"$

Recall our toy language  $L \subseteq \Sigma^*$  of well-formed parentheses:

- $\varepsilon \in L$
- If  $x, y, z \in L$  then  $xaybz \in L$

Prove that every string in  $L$  has the same number of  $a$ 's and of  $b$ 's

# Structural Induction

For every  $w \in L$  denote  $A(w)$  and  $B(w)$  the number of a's and of b's in  $w$ .

We prove that  $A(w) = B(w)$  by structural induction on  $w$

- If  $w = \varepsilon$ , then  $A(w) = B(w) = 0$
- If  $x, y, z \in L$  and  $w = xaybz$ , then:
  - The inductive hypothesis is:  
 $A(x) = B(x)$  and  $A(y) = B(y)$  and  $A(z) = B(z)$
  - $A(w) = A(x) + A(y) + A(z) + 1$
  - $B(w) = B(x) + B(y) + B(z) + 1$
  - Hence  $A(w) = B(w)$

# Recursive Functions on Trees

- $N(T)$  - number of vertices of  $T$
- $N(\varepsilon) = 0$ ;  $N(\bullet) = 1$
- $N(\bullet, T_1, T_2) = 1 + N(T_1) + N(T_2)$
  
- $Ht(T)$  – height of  $T$
- $Ht(\varepsilon) = 0$ ;  $Ht(\bullet) = 1$
- $Ht(\bullet, T_1, T_2) = 1 + \max(Ht(T_1), Ht(T_2))$

NOTE: Height definition differs from the text  
Base case  $H(\bullet) = 0$  used in text

# Structural Induction

- Prove that for every non-empty binary tree  $T$ , the following holds:

$$N(T) \leq 2^{\text{Ht}(T)} - 1$$

# Structural Induction

Claim:  $N(T) \leq 2^{\text{Ht}(T)} - 1$

- If  $T = \bullet$  then  $N(\bullet) = 1$ ,  $\text{Ht}(\bullet) = 1$ ; claim holds
- If  $T = (\bullet, T_1, T_2)$ , let  $x = \text{Ht}(T_1)$ ,  $y = \text{Ht}(T_2)$ 
  - By induction:  $N(T_1) \leq 2^x - 1$  and  $N(T_2) \leq 2^y - 1$
  - $N(T) = 1 + N(T_1) + N(T_2)$  and  $\text{H}(T) = 1 + \max(x, y)$

$$\begin{aligned} N(T) &\leq 1 + 2^x - 1 + 2^y - 1 = 2^x + 2^y - 1 \\ &\leq 2^{\text{Ht}(T)-1} + 2^{\text{Ht}(T)-1} - 1 = 2^{\text{Ht}(T)} - 1 \end{aligned}$$

# The Importance of the Height

- $N(T) \leq 2^{\text{Ht}(T)} - 1$  implies the following important property of binary trees:

$$\text{Ht}(T) \geq \log(N(T) + 1)$$

- What about the upper bound: ?

$$\text{Ht}(T) \leq ??$$

- For most algorithms we want  $\text{Ht}(T)$  “small”:

$\text{Ht}(T) \approx \log(N(T))$  is GREAT;  $\text{Ht}(T) \approx N(T)$  is BAD

# Fully balanced binary trees

- $\varepsilon$  is a FBBT.
- if  $T_1$  and  $T_2$  are FBBTs, with  $\text{Ht}(T_1) = \text{Ht}(T_2)$ , then  $(\bullet, T_1, T_2)$  is a FBBT.

- Prove at home that in a FBBT:

$$N(T) = 2^{\text{Ht}(T)} - 1$$

- This is nice, BUT: in practice can't keep trees fully balanced...

# Almost balanced trees

Recursive definition:

- $\varepsilon$  is a ABT.
- if  $T_1$  and  $T_2$  are ABTs with  
 $\text{Ht}(T_1) - 1 \leq \text{Ht}(T_2) \leq \text{Ht}(T_1) + 1$   
then  $T = (\bullet, T_1, T_2)$  is a ABT.

Let  $k_1 = \text{Ht}(T_1)$ ,  $k_2 = \text{Ht}(T_2)$ . Three cases:

$$k_1 = k_2 + 1 \text{ or } k_1 = k_2 \text{ or } k_2 = k_1 + 1$$

# Almost balanced trees

- So an “almost balanced tree”  $T$  can be quite imbalanced !
- Do we actually have  $Ht(T) \approx \log(N(T))$  ?

# Almost Balanced Binary Trees

Let  $f_k$  be the following sequence:

$$g_0 = 0, \quad g_1 = 0, \quad g_k = 1 + g_{k-1} + g_{k-2}$$

(we will compute later the sequence  $g_k$ )

Let  $T$  be an almost balanced tree. Prove the following:

$$\text{If } n = N(T) \text{ and } k = \text{Ht}(T) \text{ then } n \geq g_k$$

# Structural induction on T:

If  $n = N(T)$  and  $k = \text{Ht}(T)$  then  $n \geq g_k$

If  $T = \varepsilon$ , then  $n = 0$ ,  $k = 0$ , and  $0 \geq g_0$

If  $T = (\bullet, T_1, T_2)$ ; let  $n_i = N(T_i)$ ,  $k_i = \text{Ht}(T_i)$ , for  $i=1,2$ ;

By induction we know  $n_i \geq g_{k_i}$

- Case 1:  $k_1 = k_2 + 1$ . Then  $k = k_1 + 1$  and:

$$n = 1 + n_1 + n_2 \geq 1 + g_{k_1} + g_{k_2} = 1 + g_{k-1} + g_{k-2} = g_k$$

- Case 2:  $k_1 = k_2$ . Then  $k = k_1 + 1$  and:

$$n = 1 + n_1 + n_2 \geq 1 + g_{k_1} + g_{k_2} = 1 + g_{k-1} + g_{k-1} \geq g_k$$

- Case 3:  $k_2 = k_1 + 1$ . Then  $k = k_2 + 1$  and:

$$n = 1 + n_1 + n_2 \geq 1 + g_{k_1} + g_{k_2} = 1 + g_{k-2} + g_{k-1} = g_k$$

Where did we use  $g_1$  ? In Case 2:  $1 + 2g_{k-1} \geq g_k$ ;  $g_1 \leq 1 + 2g_0 = 1$

# Solving Recurrences

$$f_0 = 1, \quad f_1 = 1, \quad f_k = f_{k-1} + f_{k-2}$$

Characteristic equation:  $x^2 - x - 1 = 0$

Roots:  $x_{1,2} = (1 \pm \sqrt{5})/2$

$$f_k = A x_1^k + B x_2^k$$

Solve A, B from initial conditions:  $f_0=1, f_1=2$

$$f_k = 1/\sqrt{5} [(1 + \sqrt{5})/2]^k - 1/\sqrt{5} [(1 - \sqrt{5})/2]^k$$

Dominant term

Negative, but tiny

# Solving Recurrences

Solve:

$$g_0 = 0, \quad g_1 = 0, \quad g_k = 1 + g_{k-1} + g_{k-2}$$

Let  $f_k = g_k + 1$ . Then:

$$f_0 = 1, \quad f_1 = 1, \quad f_k = f_{k-1} + f_{k-2}$$

We have solved  $f_k$  already; thus  $g_k = f_k - 1$

# Almost Balanced Binary Trees

What is its height ?

$$\text{If } n = N(T) \text{ and } k = \text{Ht}(T) \text{ then}$$
$$n \geq g_k = f_k - 1 \approx 1/\sqrt{5} [(1 + \sqrt{5})/2]^k - 1$$

$$\log(n+1) \geq k \log [(1 + \sqrt{5})/2] - \log \sqrt{5}$$

$$k \lesssim \log(n+1) / \log [(1 + \sqrt{5})/2]$$
