AVL Trees - Lecture 7

2

Binary Search Tree - Best Time

- All BST operations are $O(h)$, where h is tree height
- $h \geq \lceil \log_2 N \rceil - 1$
 - › What is the best case tree?
 - › What is the worst case tree?
- So, best case running time of BST operations is $O(\log N)$

AVL Trees - Lecture 7

3

Binary Search Tree - Worst Time

- Worst case running time is $O(N)$
 - › What happens when you Insert elements in ascending order?
 - Insert: 2, 4, 6, 8, 10, 12 into an empty BST
 - › Problem: Lack of "balance":
 - compare depths of left and right subtree
 - › Unbalanced degenerate tree

AVL Trees - Lecture 7

4

Balanced and unbalanced BST

AVL Trees - Lecture 7

5

Approaches to balancing trees

- Don't balance
 - › May end up with some nodes very deep
- Strict balance
 - › The tree must always be balanced perfectly
- Pretty good balance
 - › Only allow a little out of balance
- Adjust on access
 - › Self-adjusting

AVL Trees - Lecture 7

6

Balancing Trees

- Many algorithms exist for keeping trees balanced
 - Adelson-Velskii and Landis (AVL) trees
 - Splay trees and other self-adjusting trees
 - B-trees and other multiway search trees

AVL Trees - Lecture 7

7

Perfect Balance

- Want a **complete binary tree** after every operation
- This is expensive
 - For example, insert 2 in the tree on the left and then rebuild as a complete tree

AVL Trees - Lecture 7

8

AVL - Pretty Good Balance

- AVL trees are height-balanced binary search trees
- Balance factor** of a node
 - $\text{height}(\text{left subtree}) - \text{height}(\text{right subtree})$
- An AVL tree has balance factor calculated at every node
 - For every node, heights of left and right subtree can differ by no more than 1
 - Store current heights in each node

AVL Trees - Lecture 7

9

Height of an AVL Tree

- $M(h)$ = minimum number of nodes in an AVL tree of height h .
- Basis
 - $M(0) = 1, M(1) = 2$
- Induction
 - $M(h) = M(h-1) + M(h-2) + 1$
- Solution
 - $M(h) > \phi^h - 1$ ($\phi = (1+\sqrt{5})/2 \approx 1.62$)

AVL Trees - Lecture 7

10

Proof that $M(h) \geq \phi^h$

- Basis: $M(0) = 1 > \phi^0 - 1, M(1) = 2 > \phi^1 - 1$
- Induction step.

$$\begin{aligned}
 M(h) &= M(h-1) + M(h-2) + 1 \\
 &> (\phi^{h-1} - 1) + (\phi^{h-2} - 1) + 1 \\
 &= \phi^{h-2} (\phi + 1) - 1 \\
 &= \phi^h - 1 \quad (\phi^2 = \phi + 1)
 \end{aligned}$$

AVL Trees - Lecture 7

11

Height of an AVL Tree

- $M(h) > \phi^h$ ($\phi \approx 1.62$)
- Suppose we have n nodes in an AVL tree of height h .
 - $n > M(h)$
 - $n > \phi^h - 1$
 - $\log_\phi(N+1) \geq h$ (relatively well balanced tree!!)

AVL Trees - Lecture 7

12

Node Heights

height of node = h
 balance factor = $h_{\text{left}} - h_{\text{right}}$
 empty height = -1

AVL Trees - Lecture 7

13

Node Heights after Insert 7

height of node = h
 balance factor = $h_{\text{left}} - h_{\text{right}}$
 empty height = -1

AVL Trees - Lecture 7

14

Insert and Rotation in AVL Trees

- Insert operation may cause balance factor to become 2 or -2 for some node
 - only nodes on the path from insertion point to root node have possibly changed in height
 - So after the Insert, go back up to the root node by node, updating heights
 - If a new balance factor (the difference $h_{\text{left}} - h_{\text{right}}$) is 2 or -2, adjust tree by **rotation** around the node

AVL Trees - Lecture 7

15

Single Rotation in an AVL Tree

AVL Trees - Lecture 7

16

Insertions in AVL Trees

Let the node that needs rebalancing be α .

There are 4 cases:

Outside Cases (require single rotation) :

1. Insertion into **left** subtree of **left** child of α .
2. Insertion into **right** subtree of **right** child of α .

Inside Cases (require double rotation) :

3. Insertion into **right** subtree of **left** child of α .
4. Insertion into **left** subtree of **right** child of α .

The rebalancing is performed through four separate rotation algorithms.

AVL Trees - Lecture 7

17

AVL Insertion: Outside Case

Consider a valid AVL subtree

AVL Trees - Lecture 7

18

AVL Insertion: Outside Case

Inserting into X destroys the AVL property at node j

AVL Trees - Lecture 7

19

AVL Insertion: Outside Case

Do a "rotation from left"

AVL Trees - Lecture 7

20

Single rotation from left

AVL Trees - Lecture 7

21

Outside Case Completed

"rotation from left" done!
("rotation from right" is mirror symmetric)

AVL property has been restored!

AVL Trees - Lecture 7

22

AVL Insertion: Inside Case

Consider a valid AVL subtree

AVL Trees - Lecture 7

23

AVL Insertion: Inside Case

Inserting into Y destroys the AVL property at node j

Does "rotation from left" restore balance?

AVL Trees - Lecture 7

24

AVL Insertion: Inside Case

AVL Trees - Lecture 7

25

AVL Insertion: Inside Case

Consider the structure of subtree Y...

AVL Trees - Lecture 7

26

AVL Insertion: Inside Case

Y = node i and subtrees V and W

AVL Trees - Lecture 7

27

AVL Insertion: Inside Case

We will do a "double rotation"...

AVL Trees - Lecture 7

28

Double rotation : first rotation

AVL Trees - Lecture 7

29

Double rotation : second rotation

AVL Trees - Lecture 7

30

Double rotation : second rotation

31

Implementation

AVL Trees - Lecture 7

32

Single Rotation

```
RotateFromRight(n : reference node pointer) {
  p : node pointer;
  p := n.right;
  n.right := p.left;
  p.left := n;
  n := p;
}
```

AVL Trees - Lecture 7

33

Double Rotation

- Class participation
- Implement Double Rotation in two lines.

```
DoubleRotateFromRight(n : reference node pointer) {
  ???
}
```

AVL Trees - Lecture 7

34

AVL Tree Deletion

- Similar to insertion
 - › Rotations and double rotations needed to rebalance
 - › Imbalance may propagate upward so that many rotations may be needed.

AVL Trees - Lecture 7

35

Pros and Cons of AVL Trees

Arguments for AVL trees:

1. Search is $O(\log N)$ since AVL trees are *always well balanced*.
2. The height balancing adds no more than a constant factor to the speed of insertion, deletion, and find.

Arguments against using AVL trees:

1. Difficult to program & debug; more space for height info.
2. Asymptotically faster but rebalancing costs time.
3. Most large searches are done in database systems on disk and use other structures (e.g. B-trees).
4. May be OK to have $O(N)$ for a single operation if total run time for many consecutive operations is fast (e.g. Splay trees).

AVL Trees - Lecture 7

36

Double Rotation Solution

```
DoubleRotateFromRight(n : reference node pointer) {  
  RotateFromLeft(n.right);  
  RotateFromRight(n);  
}
```

AVL Trees - Lecture 7
