Exceptions and assertions

Failure causes

Partial failure is inevitable

Goal: prevent complete failure

Structure your code to be reliable and understandable

Some failure causes:

1. Misuse of your code

Precondition violation

2. Errors in your code

Bugs, representation exposure, many more

3. Unpredictable external problems

Out of memory

Missing file

Memory corruption

How would you categorize these?

Failure of a subcomponent

No return value (e.g., list element not found, division by zero)

Avoiding errors

A precondition prohibits misuse of your code Adding a precondition weakens the spec

This ducks the problem

Does not address errors in your own code

Does not help others who are misusing your code

Removing the precondition requires specifying the behavior

Strengthens the spec

Example: specify that an exception is thrown

Defensive programming

```
Check
   precondition
   postcondition
   representation invariant
   other properties that you know to be true
Check statically via reasoning (& tools)
Check dynamically at run time via assertions
   assert index >= 0;
   assert size % 2 == 0 : "Bad size for " + toString();
Write the assertions as you write the code
```

When not to use assertions

```
Don't clutter the code
   x = y + 1;
                        // useless, distracting
   assert x == y + 1;
Don't perform side effects
   assert list.remove(x); // modifies behavior if disabled
                                       How can you test at run time
   // Better:
                                       whether assertions are enabled?
   boolean found = list.remove(x);
                                       Why would you want to do this?
   assert found;
Turn them off in rare circumstances (e.g., production code)
   "java -ea" runs Java with <u>a</u>ssertions <u>e</u>nabled
   "java" runs Java with assertions disabled (default)
   Most assertions should always be enabled
```

What to do when something goes wrong

Something goes wrong: an assertion fails Or if an assertion had been there, it would have failed Goal 1: Give information about the problem To the programmer A good error message is key! To the client code Goal 2: Prevent harm from occurring Abort: inform a human Perform cleanup actions, log the error, etc. Re-try Problem might be transient Skip a subcomputation Permit rest of program to continue Fix the problem (usually infeasible) External problem: no hope; just be informative

Internal problem: if you can fix, you can prevent

Square root without exceptions

```
// requires: x ≥ 0
// returns: approximation to square root of x
public double sqrt(double x) {
   ...
}
```

Square root with assertion

```
// requires: x ≥ 0
// returns: approximation to square root of x
public double sqrt(double x) {
   double result;
   ... // compute result
   assert (Math.abs(result*result - x) < .0001);
   return result;
}</pre>
```

Square root, specified for all inputs

```
// throws: IllegalArgumentException if x < 0
// returns: approximation to square root of x
public double sqrt(double x) throws IllegalArgumentException
  if (x < 0)
    throw new IllegalArgumentException();
Client code:
try {
  y = sqrt(-1);
} catch (IllegalArgumentException e) {
  e.printStackTrace(); // or take some other action
Caught by catch associated with nearest dynamically enclosing try
   Top-level default handler: stack trace, program terminates
```

Propagating an exception

```
// returns: x such that ax^2 + bx + c = 0
// throws: IllegalArgumentException if no real soln exists
double solveQuad(double a, double b, double c) throws
    IllegalArgumentException
{
    // No need to catch exception thrown by sqrt
    return (-b + sqrt(b*b - 4*a*c)) / (2*a);
}
```

How can clients know whether a set of arguments to solveQuad is illegal?

Exception translation

```
// returns: x such that ax^2 + bx + c = 0
   // throws: NotRealException if no real solution exists
   double solveQuad(double a, double b, double c) throws
     NotRealException
     try {
       return (-b + sqrt(b*b - 4*a*c)) / (2*a);
     } catch (IllegalArgumentException e) {
       throw new NotRealException();
   class NotRealException extends Exception {
     NotRealException() { super(); }
     NotRealException(String message) { super(message); }
     NotRealException(Throwable cause) { super(cause); }
     NotRealException(String msg, Throwable c) { super(msg, c); }
Exception chaining:
   throw new NotRealException(e);
```

Exceptions as non-local control flow

```
void compile() {
  try {
    parse();
    typecheck();
    optimize();
    generate():
  } catch (RuntimeException e) {
    Logger.log("Failed: " + e.getMessage());
  }
}
```

Informing the client of a problem

```
Special value
   null - Map.get
   -1 - indexOf
   мам — sqrt of negative number
Problems with using special value
   Hard to distinguish from real results
   Error-prone: what if the programmer forgets to check
     result?
       The value should not be legal – should cause a failure later
   Ugly
   Less efficient
A better solution: exceptions
```

Two distinct uses of exceptions

Failures

Unexpected

Should be rare with well-written client and library

Can be the client's fault or the library's

Usually unrecoverable

Special results

Expected

Unpredictable or unpreventable by client

Handling exceptions

Failures

Usually can't recover

If the condition is not checked, the exception propagates up the stack

The top-level handler prints the stack trace

Special results

Take special action and continue computing Should always check for this condition Should handle locally

Why catch exceptions locally?

Failure to catch exceptions violates modularity

Call chain: A → IntegerSet.insert → IntegerList.insert IntegerList.insert throws an exception

Implementer of IntegerSet.insert knows how list is being used Implementer of A may not even know that IntegerList exists

Procedure on the stack may think that it is handling an exception raised by a different call

Better alternative: catch it and throw it again

"chaining" or "translation"

Do this even if the exception is better handled up a level

Makes it clear to reader of code that it was not an omission

Java exceptions for failures and for special cases

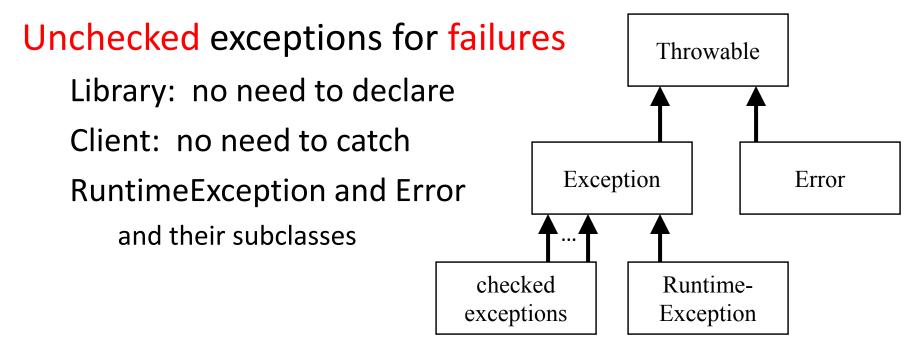

Checked exceptions for special cases

Library: must declare in signature

Client: must either catch or declare

Even if you can prove it will never happen at run time

There is guaranteed to be a dynamically enclosing catch

Avoid proliferation of checked exceptions

Unchecked exceptions are better if clients will usually write code that ensures the exception will not happen. There is a convenient and inexpensive way to avoid it.

The exception reflects unanticipatable failures

Otherwise use a checked exception

Must be caught and handled – prevents program defects Checked exceptions should be locally caught and handled Checked exceptions that propagate long distances suggests bad design (failure of modularity)

Java sometimes uses null (or NaN, etc.) as a special value Acceptable if used judiciously, carefully specified Easy to forget to check

Exceptions in review

Use an exception when

Used in a broad or unpredictable context

Checking the condition is feasible

Use a precondition when

Checking would be prohibitive

E.g., requiring that a list be sorted

Used in a narrow context in which calls can be checked

Avoid preconditions because

Caller may violate precondition

Program can fail in an uninformative or dangerous way

Want program to fail as early as possible

How do preconditions and exceptions differ, for the client?

Exceptions in review, continued

Use checked exceptions most of the time Handle exceptions sooner rather than later

Not all exceptions are errors

A program structuring mechanism with non-local jumps Used for exceptional (unpredictable) circumstances
