CSE 331 Software Design & Implementation

Hal Perkins Autumn 2012 Events, Listeners, and Callbacks (slides by Mike Ernst and David Notkin)

A design exercise

Write a typing break reminder program

Offer the hard-working user occasional reminders of the perils of Repetitive Strain Injury, and encourage the user to take a break from typing.

Naive design:

Write a method to display messages and offer exercises. Write a loop to call that method from time to time.

(Let's ignore multi-threaded solutions for this discussion)

TimeToStretch suggests exercises

```
public class TimeToStretch {
    public void run() {
        System.out.println("Stop typing!");
        suggestExercise();
    }
    public void suggestExercise() {
    }
```

Timer calls run() periodically

```
public class Timer {
  private TimeToStretch tts = new TimeToStretch();
  public void start() {
    while (true) {
       . . .
      if (enoughTimeHasPassed) {
        tts.run();
       }
       . . .
    }
}
```

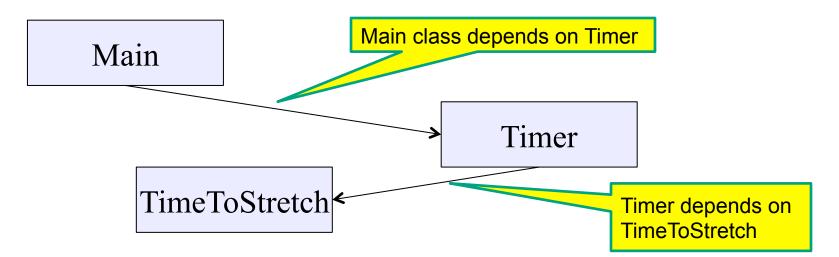

Main class puts it together

```
class Main {
  public static void main(String[] args) {
    Timer t = new Timer();
    t.start();
  }
}
```

This will work... But we can do better

Module dependency diagram (MDD)

An arrow in a module dependency diagram (MDD) indicates "depends on" or "knows about" – simplistically, "any name mentioned in the source code"

Does **Timer** really need to depend on **TimeToStretch**? Is **Timer** re-usable in a new context?

Decoupling

Timer needs to call the run method Timer doesn't need to know what the run method does Weaken the dependency of Timer on TimeToStretch Introduce a weaker specification, in the form of an interface or abstract class

```
public abstract class TimerTask {
   public abstract void run();
}
```

Timer only needs to know that something (e.g., TimeToStretch) meets the TimerTask specification

TimeToStretch (version 2)

```
public class TimeToStretch extends TimerTask {
    public void run() {
        System.out.println("Stop typing!");
        suggestExercise();
    }
```

```
public void suggestExercise() {
```

}

Timer (version 2)

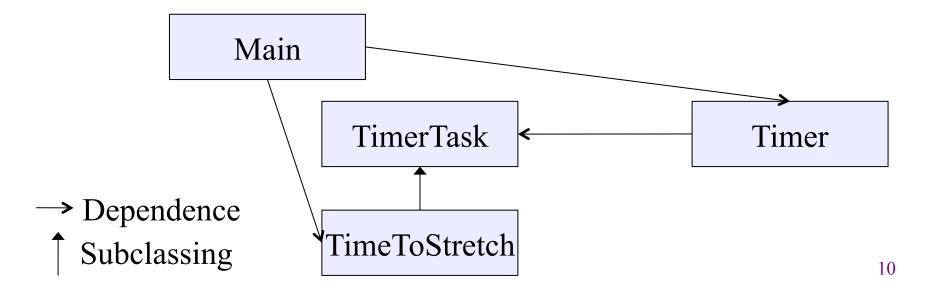

```
public class Timer {
    private TimerTask task;
    public Timer(TimerTask task) { this.task = task; }
    public void start() {
        while (true) {
            ...
            task.run();
        }
    }
}
```

Main creates the **TimeToStretch** object and passes it to **Timer**:

```
Timer t = new Timer(new TimeToStretch());
t.start();
```

Module dependency diagram (version 2)

Main still depends on Timer (is this necessary?) Main depends on the constructor for TimeToStretch Timer depends on TimerTask, not TimeToStretch Unaffected by implementation details of TimeToStretch Now Timer is much easier to reuse

The callback design pattern

TimeToStretch creates a **Timer**, and passes in a reference to itself so the **Timer** can *call it back*.

- This is a *callback* a method call from a module to a client that it notifies about some condition.
- Use a callback to invert a dependency

Inverted dependency: TimeToStretch depends on Timer (not vice versa).

Side benefit: Main does not depend on Timer

Callbacks

Synchronous callbacks:

Examples: HashMap calls its client's hashCode, equals

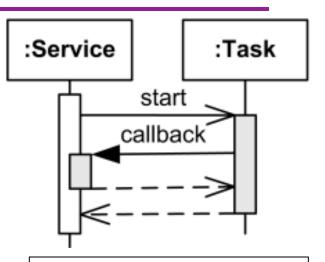

Useful when the callback result is needed immediately by the library

Asynchronous callbacks:

Examples: GUI listeners

Register to indicate interest and where to call back

Useful when the callback should be performed later, when some interesting event occurs

A synchronous callback. Time increases downward. Solid lines: calls Dotted lines: returns

TimeToStretch (version 3)

```
public class TimeToStretch extends TimerTask {
    private Timer timer;
                                            Register interest
                                             with the timer
    public TimeToStretch() {
         timer = new Timer(this);
    public void start() {
         timer.start();
                                  Callback entry point
    public void run() {
         System.out.println("Stop typing!");
         suggestExercise();
     }
```

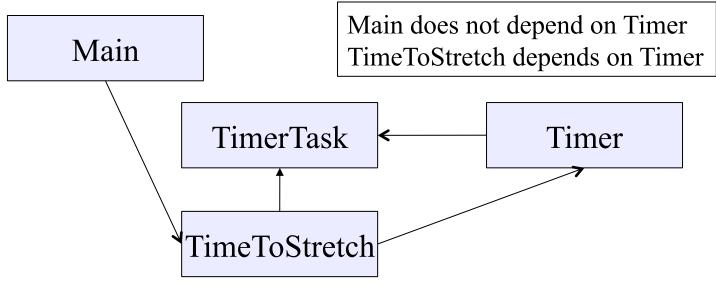

Main (version 3)

```
TimeToStretch tts = new TimeToStretch();
```

```
tts.start();
```

Use a callback to invert a dependency

This diagram shows the inversion of the dependency between **Timer** and **TimeToStretch** (compared to ver. 1)

Decoupling and design

A good design has dependences (coupling) only where it makes sense.

While you design (before you code), examine dependences.

Don't introduce unnecessary coupling.

Coupling is an easy temptation if you code first.

Suppose a method needs information from another object:

If you hack in a way to get it:

The hack might be easy to write.

It will damage the code's modularity and reusability.

More complex code is harder to understand.

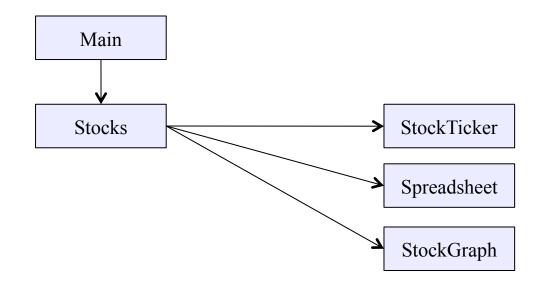

Design exercise #2

A program to display information about stocks stock tickers spreadsheets graphs Naive design: Make a class to represent stock information

That class updates all views of that information (tickers, graphs, etc.) when it changes

Module dependency diagram

Main class gathers information and stores in Stocks Stocks class updates viewers when necessary

Problem: To add/change a viewer, must change Stocks Better: insulate Stocks from the vagaries of the viewers

Weaken the coupling

What should Stocks class know about viewers?

Only needs an update method to call when things change

Old:

void updateViewers() {
 ticker.update(newPrice);
 spreadsheet.update(newPrice);
 graph.update(newPrice);
 // Edit this method whenever
 // different viewers are desired. 😒

New (uses "observer pattern"):

List<Observer> observers;

void notifyObserver() {
 for (Observer obs : observers) {
 obs.update(newPrice);

Callback

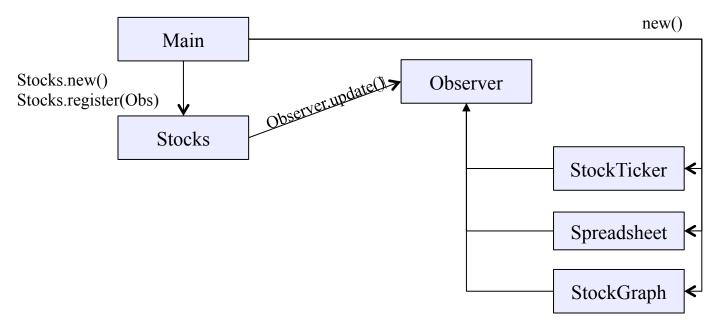

How are observers created?

interface Observer {

void update(...);

The observer pattern

Stocks not responsible for viewer creation Main passes viewers to Stocks as Observers Stocks keeps list of Observers, notifies them of changes

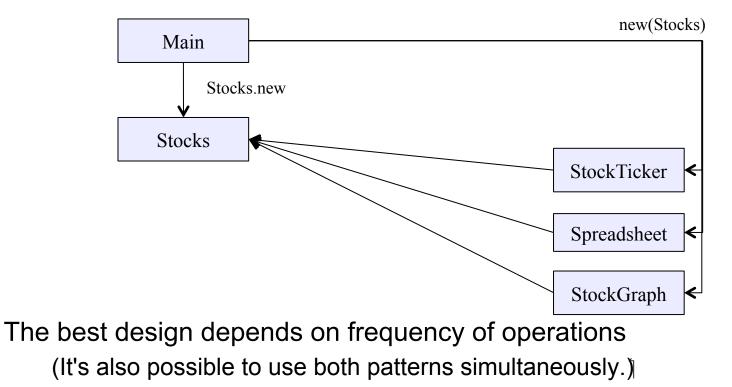

Problem: doesn't know what info each Observer needs

A different design: pull versus push

The Observer pattern implements *push* functionality

A *pull* model: give viewers access to **Stocks**, let them extract the data they need

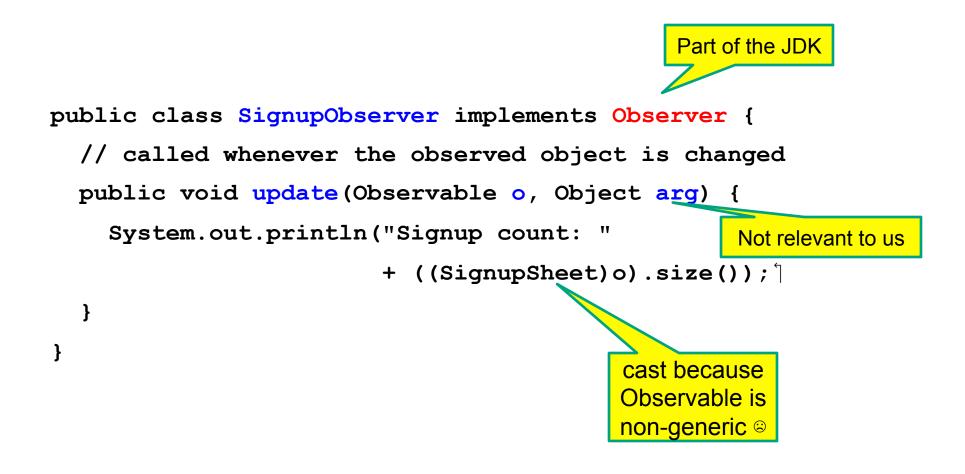

Usually need way for Stocks to tell viewers when changes happen

Another example of Observer pattern

```
Part of the JDK
// Represents a sign-up sheet of students
public class SignupSheet extends Observable {
  private List<String> students
                  = new ArrayList<String>();
  public void addStudent(String student) {
    students.add(student);
    notifyObservers();
  public int size() {
    return students.size();
```

An Observer

Using the observer

```
SignupSheet s = new SignupSheet();
s.addStudent("billg");
// nothing visible happens
s.addObserver(new SignupObserver());
s.addStudent("torvalds");
// now text appears: "Signup count: 2"
```

Java's "Listeners" (particularly in GUI classes) are examples of the Observer pattern

User interfaces: appearance vs. content

It is easy to tangle up appearance and content.

- Particularly when supporting direct manipulation (e.g., dragging line endpoints in a drawing program)
- Another example: program state stored in widgets in dialog boxes
- Neither can be understood easily or changed easily
- This destroys modularity and reusability
 - Over time, it leads to bizarre hacks and huge complexity
 - Code must be discarded
- Callbacks, listeners, and other patterns can help
