

# Specifications

*Krysta Yousoufian*

*CSE 331 Section*

*April 12, 2012*

*With material from Michael Ernst and Hal Perkins*

# Recall: Class Specifications

- Describe **abstract value**: what the class represents at an abstract level
  - What the client sees
  - What data the ADT holds
- Brief summary of the ADT
- Specfields: data fields of the ADT
  - e.g. length of Square
- Derived fields: data fields that can be computed from the spec fields
  - e.g.  $\text{area} = \text{length}^2$  of Square

# Example I: Complex Number

- Specify a `ComplexNumber` class
- Represents number  $a+bi$
- What are the abstract fields?
  - (What data does this class contain from the client's perspective?)

# Complex Number

- Specify a `ComplexNumber` class
- Represents number  $a+bi$
- What are the abstract fields?
  - **Real part,  $a$**
  - **Imaginary part,  $b$**

# Let's formalize it

```
/**  
 * ??????????????????  
 */  
public class ComplexNumber {  
    ...  
}
```

# Let's formalize it

```
/**  
 * ??????????????????  
 */  
public class ComplexNumber {  
    ...  
}
```

We don't need to know internal rep. to write client specs (why?)

# Let's formalize it

```
/**  
 * ??????????????????  
 */  
public class ComplexNumber {  
    ...  
}
```

We don't need to know internal rep. to write client specs (why?)

See [ComplexNumberI.java](#)

# Recall: Abstraction Function

- Specfields may not map directly to representation fields
  - Square has **length** specfield but not necessarily `private int length;`
- Internal representation can be anything as long as it somehow encodes the abstract value / specfields
- Abstraction function: a **mapping** from **internal state** to **abstract value**

# Recall: Representation Invariant

- Constrains an object's internal state
- Defines what must be true for abstraction function to hold
- If representation invariant is violated:
  - Object is “broken” – doesn't map to any abstract value

# Let's implement ComplexNumber

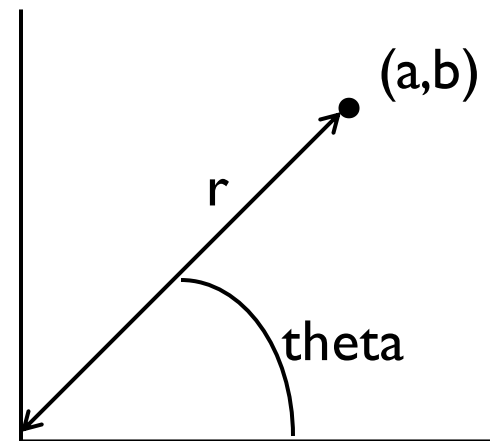

- Complex number often represented as point in Cartesian coordinate plane
- Possible representations:

$(x, y)$

Cartesian coordinates

$(\text{theta}, r)$

Polar coordinates

# Implementation #1: Cartesian

- $(x,y)$  coordinates
  - $x + yi$
- What is the AF?
- What is the RI?

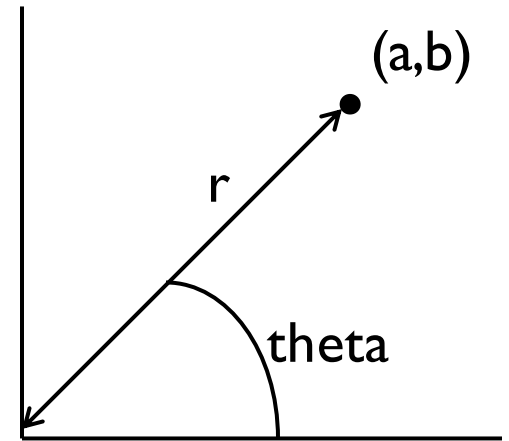

# Implementation #1: Cartesian

- (x,y) coordinates
  - $x + yi$
- What is the AF?
- What is the RI?
  - RI is `true` – object cannot be in an invalid state!
- See [ComplexNumberI.java](#)

# Implementation #2: Polar

- (theta, r)
  - $a: \text{rad} * \cos(\text{theta})$
  - $b: \text{rad} * \sin(\text{theta})$
- What is the AF?
- What is the RI?
- What should go in checkRep()?

# Implementation #2: Polar

- (theta, r)
  - $a: \text{rad} * \cos(\text{theta})$
  - $b: \text{rad} * \sin(\text{theta})$
- What is the AF?
- What is the RI?
- What should go in checkRep()?
- [See ComplexNumber2.java](#)

## Example 2: Circle

- Circle on the Cartesian coordinate plane

# Circle: Class Specification

What are the abstract fields?

# Circle: Class Specification

What are the abstract fields?

- Center point
- Radius
- Properties derived from these fields:  
circumference, area

# Let's formalize it

```
/**  
 * ??????????????????  
 */  
public class Circle {  
    ...  
}
```

# Let's formalize it

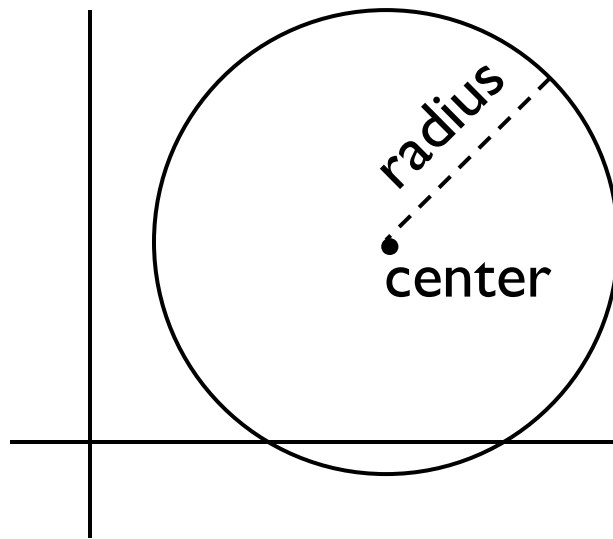

```
/**  
 * ??????????????????  
 */  
public class Circle {  
    ...  
}
```

- See [Circle I.java](#)

# Writing AF, RI: Implementation I

- Store center, radius directly
- Write the abstraction function, rep. invariant
- [CircleI.java](#)

# Writing AF, RI: Implementation 2

- Store center, edge point
- Write the abstraction function, rep. invariant
- [Circle2.java](#)

# Writing AF, RI: Implementation 3

- Store corners of square inscribed in circle
- Write the abstraction function, rep. invariant
- [Circle3.java](#)

## Example 3: Map

- Collection of <key, value> pairs
- Perform lookups by key
- What does the client see?

# Example 3: Map

- Collection of <key, value> pairs
- Perform lookups by key
- What does the client see?
  - A collection of elements with some special properties – doesn't really have "specfields"
  - See [IntTreeMap.java](#)

# Implementation: IntTreeMap

- **DISCLAIMER:** when *using* a map, TreeMaps are almost never what you want!
- HashMaps have much better performance
- But TreeMaps make a better AF/RI example here

# Method Specifications

Precondition

@requires

determines the conditions under which the method may be invoked

Frame Condition

@modifies

a **list** of specfields identifying what might be modified by the method

Postcondition

@return

describes the value that gets returned, if any

@throws

each of these lists an exception and the conditions under which it will be thrown

@effects

any side effects that may result from invoking the method

# General Guidelines

- Javadoc specs (`/** ... */`) are **external** documentation
  - Visible to the client
  - Can be used to generate code-free documentation pages (e.g. [Java API](#))
- So, Javadoc should only refer to what the client sees
  - Specfields / abstract value
  - Never instance fields or other internal details
- When referring to implementation details, use regular comments (`//`)
  - This includes **AF** and **RI**

# General Guidelines, cont.

- Specs exist to help humans understand your code
- Crucial that they are easy to read and understand
- Be precise but concise
- Use formal mathematical notation or plain English – whichever is easier to understand
