Procedure specifications

CSE 331
University of Washington

Michael Ernst
2 goals of software system building

1. Building the **right system**
   - Does the program meet the user’s needs?
   - Determining this is called **validation**

2. Building the **system right**
   - Does the program meet the specification?
   - Determining this is called **verification**

Our focus in CSE 331: creating a correctly functioning artifact
The challenge of scaling software

• Small programs are simple and malleable
  – easy to write
  – easy to change

• Big programs are (often) complex and inflexible
  – hard to write
  – hard to change

• Why does this happen?
  – Because interactions become unmanageable

• How do we keep things simple and malleable?
  – Divide and conquer
Modularity tames complexity

Two ways to view a system:
- The client's view (how to use it)
- The implementer's view (how to build it)
A discipline of modularity

Apply implementer and client views to system *parts*
  – While implementing one part, consider yourself a client of any other parts it depends on
  – Act as if ignorant of its implementation
  – This minimizes interactions between parts

Formalized through a *specification*

---

**Client**
- makes calls

**API / interface / specification**
- add()
- remove()
- size()

**Client code**

**Implementation**
- **Module 1**
  - toString()
- **Module 2**
  - put()
  - get()
  - private helper()
- **Module 3**
  - int aField;
A specification is a contract

• A set of requirements agreed to by the user and the manufacturer of the product
  – Describes their expectations of each other

• Facilitates simplicity by *two-way* isolation
  – Isolate client from implementation details
  – Isolate implementer from how the part is used
  – Discourages implicit, unwritten expectations

• Facilitates change
  – The code can change
  – The specification cannot
Isn’t the interface sufficient?

The interface defines the boundary between the implementers and users:

```java
public interface List<E> {
    public int get(int);
    public void set(int, E);
    public void add(E);
    public void add(int, E);
    ...
    public static boolean sub(List<T>, List<T>);
}
```

Interface provides the syntax
But nothing about the behavior and effects
Why not just read code?

```java
boolean sub(List<?> src, List<?> part) {
    int part_index = 0;
    for (Object o : src) {
        if (o.equals(part.get(part_index))) {
            part_index++;
            if (part_index == part.size()) {
                return true;
            }
        } else {
            part_index = 0;
        }
    }
    return false;
}

Why are you better off with a specification?
Code is complicated

• Code gives more detail than needed by the client
• Understanding or even reading every line of code is an excessive burden
  – Suppose you had to read the source code of Java libraries in order to use them
  – Same applies to developers of different parts of the libraries
• Client cares only about what the code does, not how it does it
Code is ambiguous

• Code seems unambiguous and concrete
  – But which details of code's behavior are essential, and which are incidental?

• Code invariably gets rewritten
  – Client needs to know what they can rely on
    • What properties will be maintained over time?
    • What properties might be changed by future optimization, improved algorithms, or bug fixes?
  – Implementer needs to know what features the client depends on, and which can be changed
Comments are essential

Most comments convey only an informal, general idea of what the code does:

```java
// Check whether "part" appears as a sub-sequence in "src".
boolean hasSublist(List<?> src, List<?> part) {
    ...
}
```

Problem: ambiguity remains
  – e.g. what if src and part are both empty lists?
From vague comments to specifications

• **Properties of a specification:**
  – The client agrees to rely *only* on information in the description when using the part
  – The implementer of the part promises to support everything in the description
    • otherwise is perfectly at liberty

• **When code lacks a specification**
  – Clients often work out what a method/class does in ambiguous cases by simply running it, then depending on the results
  – This leads to bugs and to programs with unclear dependencies, reducing simplicity and flexibility
An implementation of hasSublist

// Check whether "part" appears as a sub-sequence in "src".
<T> boolean hasSublist(List<T> src, List<T> part) {
    int part_index = 0;
    for (T elt : src) {
        if (elt.equals(part.get(part_index))) {
            part_index++;
            if (part_index == part.size()) {
                return true;
            }
        } else {
            part_index = 0;
        }
    }
    return false;
}
A more careful description of hasSublist

// Check whether “part” appears as a
// sub-sequence in “src”.

needs to be given some caveats (why?):

// * src and part cannot be null
// * If src is an empty list, always returns false.
// * Results may be unexpected if partial matches
//   can happen right before a real match; e.g.,
//   list (1,2,1,3) will not be identified as a
//   sub sequence of (1,2,1,2,1,3).

or replaced with a more detailed description:

// This method scans the “src” list from beginning
// to end, building up a match for “part”, and
// resetting that match every time that...
It’s better to **simplify** than to **describe** complexity

A complicated description suggests poor design

Rewrite `hasSublist()` to be more sensible, and easier to describe:

```java
// returns true iff sequences A, B exist such that
// src = A + part + B
// where “+” is sequence concatenation
boolean hasSublist(List<?> src, List<?> part)
```

Mathematical flavor is not necessary, but can help avoid ambiguity

“Declarative” style is important
  – avoid reciting or depending on implementation details
Sneaky fringe benefit of specs #1

• The discipline of writing specifications changes the incentive structure of coding
  – rewards code that is easy to describe and understand
  – punishes code that is hard to describe and understand (even if it is shorter or easier to write)

• If you find yourself writing complicated specifications, it is an incentive to redesign
  – sub() code that does exactly the right thing may be slightly slower than a hack that assumes no partial matches before true matches – but the cost of forcing client to understand the details is too high
Examples of specifications

• Javadoc
  – Sometimes can be daunting; get used to using it
• Javadoc convention for writing specifications
  – method signature (prototype)
  – text description of method
  – @param: description of what gets passed in
  – @return: description of what gets returned
  – @throws: list of exceptions that may occur
Example: Javadoc for String.contains

public boolean contains(CharSequence s)

Returns true if and only if this string contains the specified sequence of char values.

Parameters:

s - the sequence to search for

Returns:

true if this string contains s, false otherwise

Throws:

NullPointerException

Since:

1.5
CSE 331 specifications

• The “precondition”: constraints that hold before the method is called (if not, all bets are off)
  – requires: spells out any obligations on client

• The “postcondition”: constraints that hold after the method is called (if the precondition held)
  – modifies: lists objects that may be affected by method; any object not listed is guaranteed to be untouched
  – throws: lists possible exceptions (Javadoc uses this too)
  – effects: gives guarantees on the final state of modified objects
  – returns: describes return value (Javadoc uses this too)
Example 1

static int change(List<T> lst, T oldelt, T newelt)

  requires lst, oldelt, and newelt are non-null.
  oldelt occurs in lst.

  modifies lst

  effects change the first occurrence of oldelt in lst to newelt
  & makes no other changes to lst

  returns the position of the element in lst that was oldelt and now newelt

  static int change(List<T> lst, T oldelt, T newelt) {
      int i = 0;
      for (T curr : lst) {
        if (curr == oldelt) {
          lst.set(newelt, i);
          return i;
        }
      }
      i = i + 1;
      return -1;
  }
Example 2

static List<Integer> listAdd(List<Integer> lst1, List<Integer> lst2)

  requires lst1 and lst2 are non-null.
  lst1 and lst2 are the same size.

  modifies none

  effects none

  returns a list of the same size where the i-th element is
  the sum of the i-th elements of lst1 and lst2

static List<Integer> listAdd(List<Integer> lst1, List<Integer> lst2) {
  List<Integer> res = new ArrayList<Integer>();
  for(int i = 0; i < lst1.size(); i++) {
    res.add(lst1.get(i) + lst2.get(i));
  }
  return res;
}
Example 3

```java
static void listAdd2(List<Integer> lst1, List<Integer> lst2) {
    for(int i = 0; i < lst1.size(); i++) {
        lst1.set(i, lst1.get(i) + lst2.get(i));
    }
}
```
public static int binarySearch(int[] a, int key)

Searches the specified array of ints for the specified value using the binary search algorithm. The array must be sorted (as by the sort method, above) prior to making this call. If it is not sorted, the results are undefined. If the array contains multiple elements with the specified value, there is no guarantee which one will be found.

Parameters:

   a - the array to be searched.

   key - the value to be searched for.

Returns:

   index of the search key, if it is contained in the list; otherwise, 
   (- (insertion point) - 1). (long description...)
Simpler binarySearch specification

public static int binarySearch(int[] a, int key)

requires: a is sorted in ascending order
returns:
  – some i such that a[i] = key if such an i exists,
  – otherwise -1

(Returning (-(insertion point) – 1) is an invitation to bugs and confusion. See the full Javadoc. The designers had a reason; what was it, and what are the alternatives? We'll return to the topic of exceptions and special values in a later lecture.)
Upgrading a library

- Your program uses a library
- Can you use a different library?
- Can you use a new version?

We want an objective test

- You can upgrade if the specification is **stronger**
  - It makes at least as many promises
  - Example:
    - Weaker spec: returns the elements
    - Stronger spec: returns the elements **in sorted order**
Two specifications for find

int find(int[] a, int value);

• specification A
  – requires: value occurs in a
  – returns: some i such that a[i] = value

• specification B
  – requires: value occurs in a
  – returns: smallest i such that a[i] = value

int find(int[] a, int value) {
    for (int i=0; i<a.length; i++) {
        if (a[i] == value) return i;
    }
    return -1;
}
Two specifications for find

```java
int find(int[] a, int value)

• specification A
  – requires: value occurs in a
  – returns: some i such that a[i] = value

• specification C
  – returns: some i such that a[i]=value, or -1 if value is not in a
```

```java
int find(int[] a, int value) {
    for (int i=0; i<a.length; i++) {
        if (a[i]==value) return i;
    }
    return -1;
}
```
Stronger and weaker specifications

A stronger specification:

• promises more
  – Effects clause is harder to satisfy, and/or fewer objects in modifies clause
  – Consequence: Harder to implement

• asks less of the client
  – Requires clause is easier to satisfy

• is harder to implement but easier to use
  – more guarantees, more predictable
Substitutability

Suppose that:
- \( I_1 \) and \( I_2 \) satisfy \( S \)
- \( P \) uses \( I_1 \) as a component
  - And relies only on specification \( S \)

Then \( P \) can use \( I_2 \)

Further suppose that
- \( I_3 \) satisfies \( S_3 \) which is stronger than \( S \)

Then \( P \) can use \( I_3 \)

Fact: If specification \( S_3 \) is stronger than \( S_1 \), then for any implementation \( I \),
- \( I \) satisfies \( S_3 \) \( \Rightarrow \) \( I \) satisfies \( S_1 \)
Designing specifications

• There can be different specifications for the same implementation
  – Specification declares which properties are essential
    • The implementation leaves that ambiguous
  – Clients know what they can rely on, implementers know what they are committed to

• Which is better: a strong or a weak specification?
  – It depends!
  – Criteria: simple, promotes reuse & modularity, efficient
Sneaky fringe benefit of specs #2

• Specification means that client doesn't need to look at implementation
  – So the code may not even exist yet!

• Write specifications first, make sure system will fit together, and then assign separate implementers to different modules
  – Allows teamwork and parallel development
  – Also helps with testing, as we'll see soon
