- HW2 due tonight 10 pm
- Wednesday, July 4 is Independence Day 
 - No lecture
- Section Thursday, July 5
- HW3 due Thursday, July 5 at 10 pm
 - Seek HW3 help on Tuesday; no office hours Wednesday!
- Reading 3 posted on website
 - Quiz 3 (coming soon!) due Thursday, July 5 at 10 pm

Motivation

Review

lec04

Method Specification
(abstraction)

Method Body
(concrete code)

lec05

Abstract Data Type
(abstraction)

Data Structure
(concrete code)

Example: CharSet Abstraction

```
// Overview: A CharSet is a finite mutable set of Characters
// @effects: creates a fresh, empty CharSet
public CharSet() {...}

// @modifies: this
// @effects: this_post = this_pre + {c}
public void insert(Character c) {...}

// @modifies: this
// @effects: this_post = this_pre - {c}
public void delete(Character c) {...}

// @return: (c ∈ this)
public boolean member(Character c) {...}
// @return: cardinality of this
public int size() {...}
```

set – see Wolfram
Alpha definition

set union

set difference

Informal notation warning

Charset Representation Invariant

```
class CharSet {
    // Rep invariant:
    // this.elts has no nulls and no duplicates
    private List<Character> elts = ...
    ...
}
```

Rep inv. constrains structure, not meaning

An implementation of `insert` that preserves the rep invariant:

```
public void insert(Character c) {
    Character cc = new Character(encrypt(c));
    if (!elts.contains(cc))
        elts.addElement(cc);
}

public boolean member(Character c) {
    return elts.contains(c);
}
```

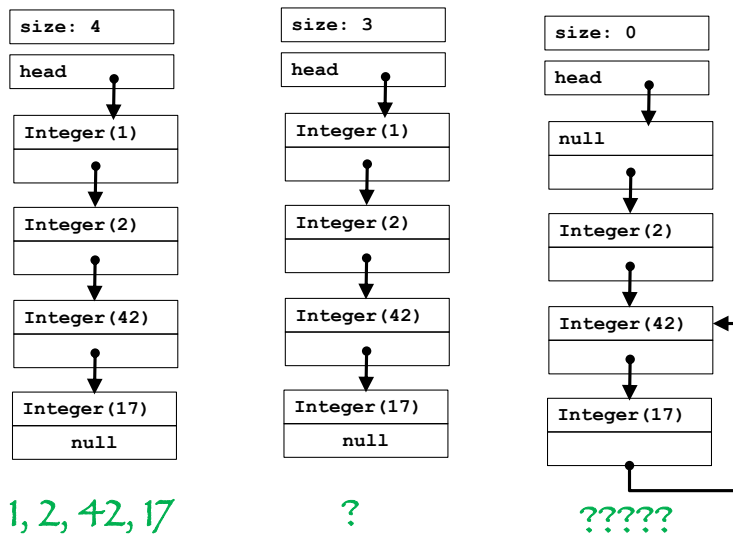

```
CharSet s = new CharSet();
s.insert('a');
if (s.member('a'))
    ...
```

Program is wrong

- Clients observe incorrect behavior
- What client code exposes the error?
- Where is the error?
- We must consider the *meaning*
- The *abstraction function* helps us

An ADT has an abstract value

Abstract Value: An Int List is a finite sequence of integer values

Connecting implementations to specs

Representation Invariant: maps Object \rightarrow boolean

lec06

- Indicates if an instance is *well-formed*
- Defines the set of valid concrete values
- Only values in the valid set make sense as implementations of an abstract value
- **For implementors/debuggers/maintainers of the abstraction: no object should ever violate the rep invariant**
 - Such an object has no useful meaning

Abstraction Function: maps Object \rightarrow abstract value

lec07
(today)

- What the data structure *means* as an abstract value
- How the data structure is to be interpreted
- Only defined on objects meeting the rep invariant
- **For implementors/debuggers/maintainers of the abstraction:** Each procedure should meet its spec (abstract values) by “doing the right thing” with the concrete representation

Functions

Set

- An unordered collection of objects

$$S = \{3, 1, 2, \text{mouse}\}$$

- An object can be in the set or not

$$3 \in S \quad -1 \notin S$$

\in = “element of”

- Set builder notation

$$T = \{x \mid x \in S \text{ and } x \text{ is an integer}\}$$

$$= \{2, 1, 3\}$$

\mid = “such that”

- Some familiar sets

$$\mathbb{Z} = \{\dots -1, 0, 1, 2, \dots\} \text{ “the integers”}$$

$$\mathbb{Q} = \{p/q \mid p, q \in \mathbb{Z}\} \text{ “the rational numbers”}$$

Function

- A relation that uniquely associates members of one set with members of another set [Wolfram]

$$F : S \rightarrow Y \quad \text{"F maps S to Y"}$$

Range: {animal, number}

Example Function

$$F : \mathbb{R} \rightarrow \mathbb{R}$$

$$F(x) = x^2$$

$$F(x) = x^2$$

passes vertical line test

Example NOT Function

Inverse of $F(x) = x^2$

$$y = \pm \sqrt{x}$$

$$\begin{aligned} \sqrt{25} &= 5 \\ \sqrt{25} &= -5 \end{aligned}$$

Does not pass vertical line test – Not a function!

Functions in Math and Programming

- In programming, the term “function” is often loosely used
- Related to the concepts of “method” and “subroutine”

```
float square(float x) {
    return x * x;
}
```

This method implements a mathematical function

```
void greet(String name) {
    System.out.println("Hello, " + name);
}
```

This method does not implement a mathematical function

Abstraction Functions

Abstraction Function

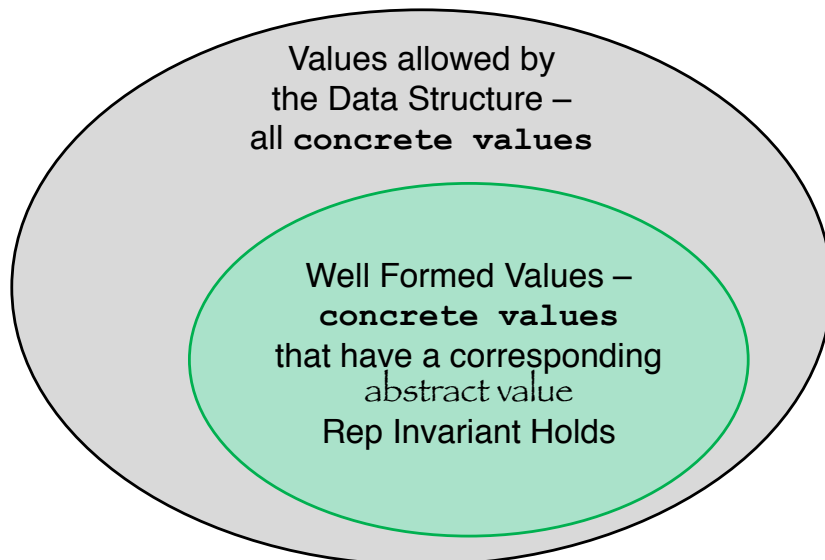

The **abstraction function** maps concrete representations to the abstract values they represent

AF: concrete rep \rightarrow abstract value

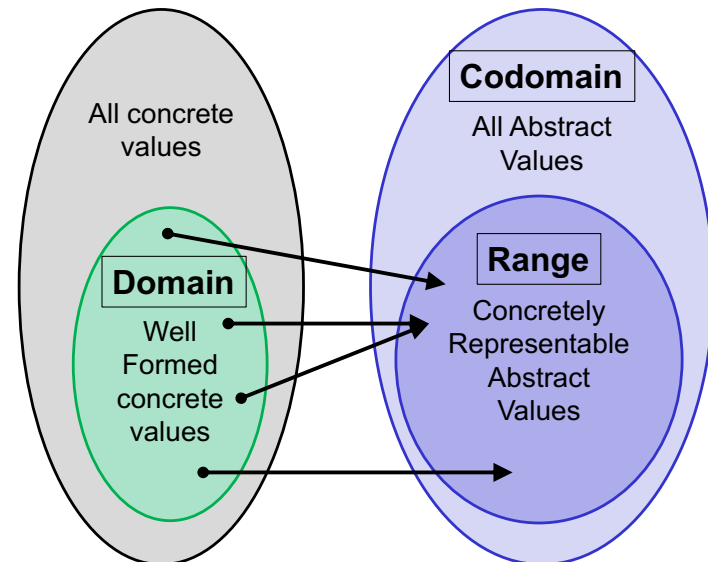

AF(CharSet this) = { c | c is contained in this.elts }
“set of Characters contained in this.elts”

- The abstraction function lets us reason about what [concrete] methods do in terms of the clients' [abstract] view
 - Makes sure that all methods use the rep in the same way
- Math concept of function, not programming concept of function
 - AF not implementable in code since range is abstract values

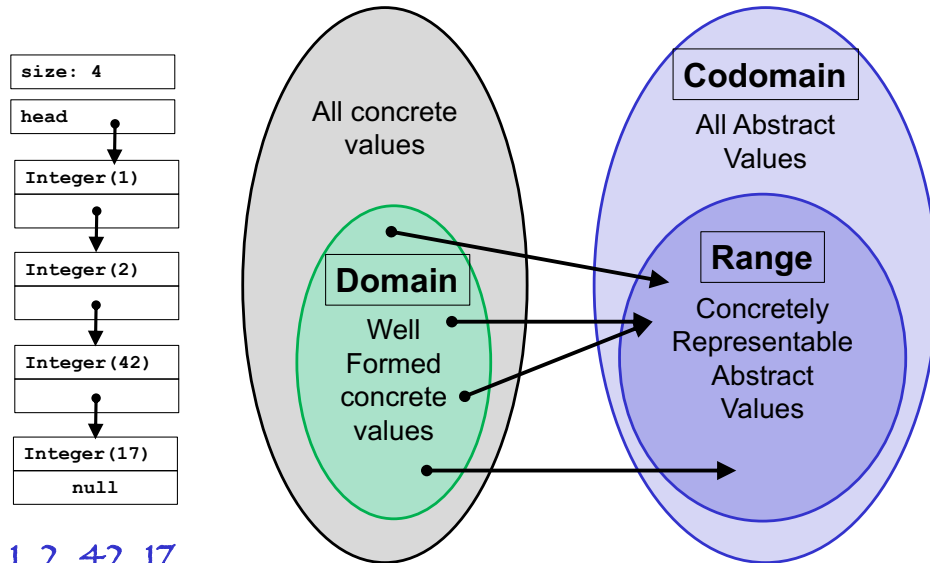

Abstraction Function

Abstraction Function

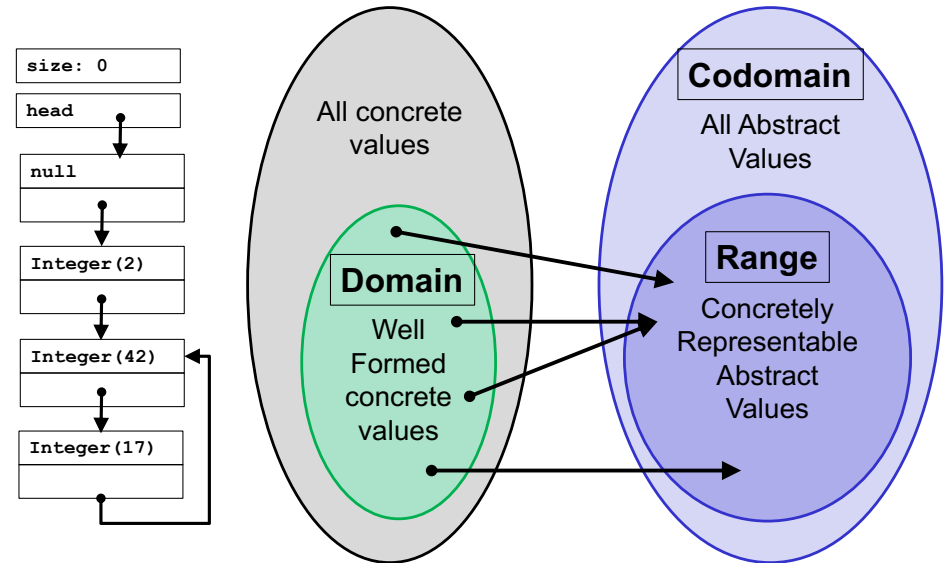

Abstraction Function

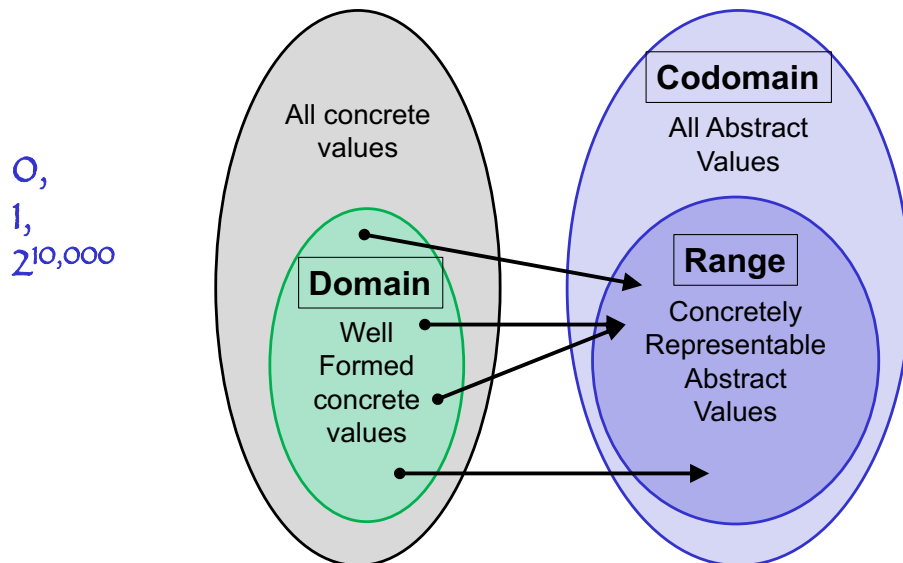

1, 2, 42, 17

Abstraction Function

Abstraction Function

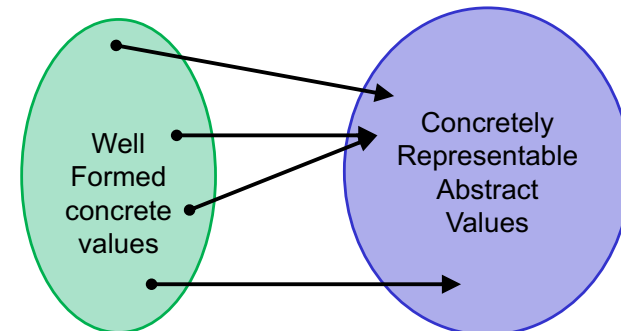

0,
1,
210,000

Summary so far:

The **abstraction function** maps concrete representations to the abstract values they represent

AF: concrete rep \rightarrow abstract value

The abstraction function is a function

Why do we map concrete to abstract and not vice versa?

- It's not a function in the other direction
 - Example: lists $[a, b]$ and $[b, a]$ might each represent the set $\{a, b\}$
- It's not as useful in the other direction
 - Purpose is to reason about whether our methods are manipulating concrete representations correctly in terms of the abstract specifications

Writing an abstraction function

Domain: all representations that satisfy the rep invariant

Range: concretely representable abstract values

Overview section of the specification should provide a notation of writing abstract values

- Could implement a method for printing in this notation
 - Useful for debugging
 - Often a good choice for `toString`

Abstraction Function and Stack

```

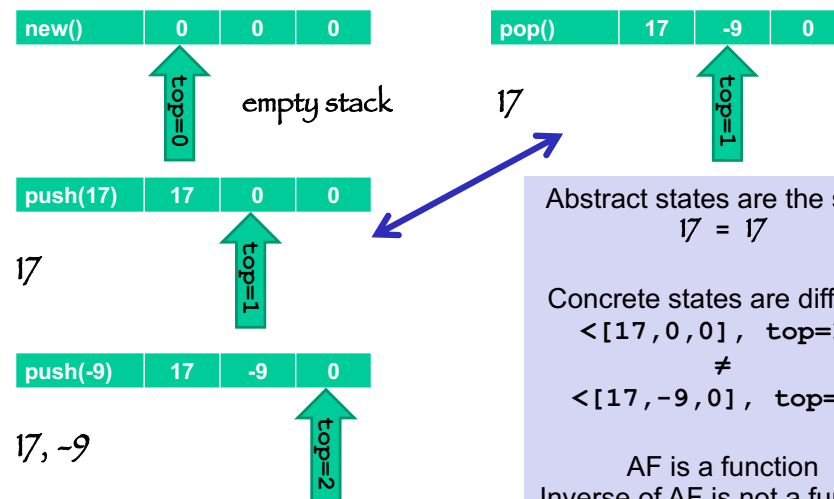

/** A last-in, first-out stack. A typical stack is
    e0, e1, ... en
    where en is the top element of the stack and is most
    recently pushed and first available to be popped. */
public class Stack {
    // Rep invariant:
    // 0 <= this.top <= this.a.length
    // this.a != null
    // Abstraction Function:
    // AF(this) = A last-in, first-out stack
    // defined by an ordered sequence of integers
    // this.a[0] ... this.a[this.top-1]
    // where the rightmost integer in the
    // sequence is at the top of the stack
    private int[] a;
    private int top;
    ...
}
    
```

implicit: the number of elements in the stack is `top`

implicit: `top` points to the array element just "after" the top of the stack

Stack AF example

recall: `top` points to the array element just after the top of the stack

Abstract states are the same
 $17 = 17$

Concrete states are different
 $\langle [17, 0, 0], \text{top}=1 \rangle$
 \neq
 $\langle [17, -9, 0], \text{top}=1 \rangle$

AF is a function
 Inverse of AF is not a function

Benevolent side effects

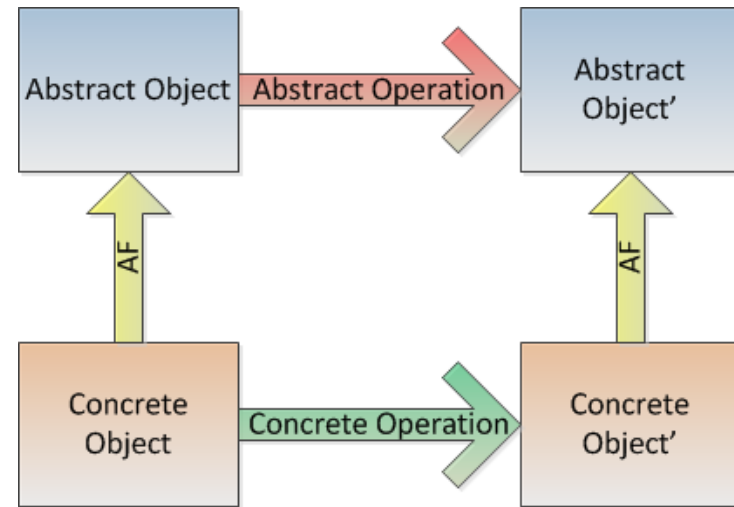

Different implementation of `member`:

```
boolean member(Character c1) {
    int i = elts.indexOf(c1);
    if (i == -1)
        return false;
    // move-to-front optimization
    Character c2 = elts.elementAt(0);
    elts.set(0, c1);
    elts.set(i, c2);
    return true;
}
```

- Move-to-front speeds up repeated membership tests
- Mutates rep, but does not change *abstract* value
 - AF maps both reps to the same abstract value
 - Precise reasoning/explanation for “clients can’t tell”

Abstract and Concrete operations

Abstraction Function and Charset

The AF tells us what the rep means...

```
public void insert(Character c) {
    Character cc = new Character(encrypt(c));
    if (!elts.contains(cc))
        elts.addElement(cc);
}
```

AF(this) = { c | encrypt(c) is contained in this.elts }

```
public boolean member(Character c) {
    return elts.contains(c);
}
```

AF(this) = { c | c is contained in this.elts }

The two methods assume different abstraction functions! BAD!!!

Charset Abstraction Function

```
class Charset {
    // Rep invariant:
    //   this.elts has no nulls and no duplicates
    // Abstraction Function:
    // AF(this) = { c | c is contained in this.elts }
    private List<Character> elts = ...
    ...
}
```

- Defined in terms of the representation (`this.elts`)
- Internal comment (not javadoc)
 - located just inside of the class definition at the very beginning
- Now we can re-implement `insert` to respect the AF

Data Abstraction: Summary

Representation Invariant describes what makes the concrete representation valid (green area)

Abstraction Function maps valid concrete values to abstract values

- Neither one is part of the ADT's specification
- Both are needed to reason an implementation satisfies the specification

Closing

Closing Announcements

- HW2 due tonight 10 pm
- HW3 due Thursday, July 5 at 10 pm
- Quiz 3 (coming soon!) due Thursday, July 5 at 10 pm

- Happy Independence Day!
