# Callbacks

## The limits of scaling

What prevents us from building huge, intricate structures that work perfectly and indefinitely?

- Not just friction
- Not just gravity
- Not just wear-and-tear

... it's the difficulty of **managing complexity!**

So we split designs into sensible parts and reduce interaction among the parts

- More *cohesion* within parts
- Less *coupling* across parts

## Concept Overview

**Coupling** – dependency between different parts

- Use coupling only where necessary
- Decouple needlessly coupled components

**Reusability**

- Uncoupled components are more reusable

**Modularity**

- The resulting design is modular because each component does its own functionality (no more, no less)

**Callbacks**

- The concept of passing in a method that will be called later
- (to be illustrated soon)

Today we will apply the concept of callbacks to decouple needlessly coupled components!

## Design exercise #1

Write a typing-break reminder program

*Offer the hard-working user occasional reminders of the perils of Repetitive Strain Injury, and encourage the user to take a break from typing.*

## Design exercise #1

Write a typing-break reminder program

*Offer the hard-working user occasional reminders of the perils of Repetitive Strain Injury, and encourage the user to take a break from typing.*

Naive design:

- Make a method to display messages and offer exercises
- Make a loop to call that method from time to time

(Let's ignore multithreaded solutions for this discussion)

## TimeToStretch suggests exercises

```
public class TimeToStretch {  
    public void run() {  
        System.out.println("Stop typing!");  
        suggestExercise();  
    }  
    public void suggestExercise() {  
        ...  
    }  
}
```

## Timer calls run () periodically

```
public class Timer {  
    private TimeToStretch tts = new TimeToStretch();  
    public void start() {  
        while (true) {  
            ...  
            if (enoughTimeHasPassed) {  
                tts.run();  
            }  
            ...  
        }  
    }  
}
```

## Main class puts it together

```
class Main {  
    public static void main(String[] args) {  
        Timer t = new Timer();  
        t.start();  
    }  
}
```

This program, as designed, will work...  
But we can do better

## Module dependency diagram (MDD)

An arrow in a module dependency diagram (MDD) indicates “depends on” or “knows about”

- Simplistically: “any name mentioned in the source code”

What's wrong with this diagram?

- Does `Timer` really need to depend on `TimeToStretch`?
- Is `Timer` re-usable in a new context?

# Decoupling

Timer needs to call the run method

- Timer does *not* need to know what the run method does

Weaken the dependency of Timer on TimeToStretch

- Introduce a weaker specification, in the form of an interface or abstract class

```
public abstract class TimerTask {  
    public abstract void run();  
}
```

Timer only needs to know that something (e.g., TimeToStretch) meets the TimerTask specification

# TimeToStretch (version 2)

```
public class TimeToStretch extends TimerTask {  
    public void run() {  
        System.out.println("Stop typing!");  
        suggestExercise();  
    }  
  
    public void suggestExercise() {  
        ...  
    }  
}
```

# Timer (version 2)

```
public class Timer {  
    private TimerTask task;  
    public Timer(TimerTask task) {  
        this.task = task;  
    }  
    public void start() {  
        while (true) {  
            ...  
            task.run();  
        }  
    }  
}
```

Main creates a TimeToStretch object and passes it to Timer:

```
Timer t = new Timer(new TimeToStretch());  
t.start();
```

Pass timer task into timer

# Module dependency diagram (version 2)

- Timer depends on TimerTask, not TimeToStretch
  - Unaffected by implementation details of TimeToStretch
  - Now Timer is much easier to reuse
  - Main depends on the constructor for TimeToStretch
- Main still depends on Timer (is this necessary?)

# Callbacks

Callback: “Code” provided by client to be used by library

- In Java, pass an object with the “code” in a method

*Synchronous* callbacks:

- Examples: `HashMap` calls its client’s `hashCode`, `equals`
- Useful when library needs the callback result immediately

*Asynchronous* callbacks:

- Examples: GUI listeners
- `Register` to indicate interest and where to call back
- Useful when the callback should be performed later, when some interesting event occurs

# The callback design pattern

Going farther: use a callback to *invert the dependency*

`TimeToStretch` creates a `Timer`, and passes in a reference to *itself* so the `Timer` can *call it back*

- This is a *callback* – a method call from a module to a client that it notifies about some condition

The callback *inverts a dependency*

- Inverted dependency: `TimeToStretch` depends on `Timer` (not vice versa)
  - Less obvious coding style, but more “natural” dependency
- Side benefit: `Main` does not depend on `Timer`

# TimeToStretch (version 3)

```
public class TimeToStretch extends TimerTask {
    private Timer timer;
    public TimeToStretch() {
        timer = new Timer(this);
    }
    public void start() {
        timer.start();
    }
    public void run() {
        System.out.println("Stop typing!");
        suggestExercise();
    }
    ...
}
```

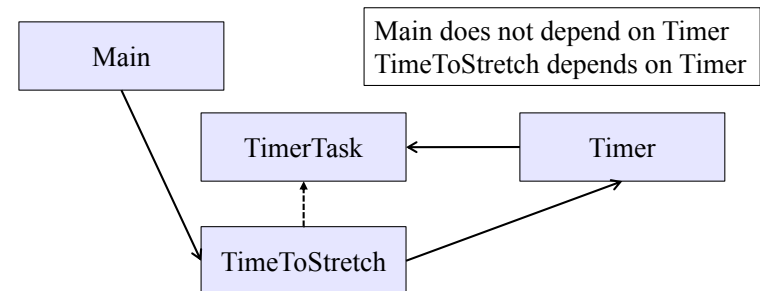

Pass self into timer (“Registration”)

Callback entry point

# Main (version 3)

```
TimeToStretch tts = new TimeToStretch();
tts.start();
```

- Uses a callback in `TimeToStretch` to invert a dependency
- This MDD shows the inversion of the dependency between `Timer` and `TimeToStretch` (compare to version 1)

## Version 1 again

- Before dependency inversion:

## For the sake of illustration

- The dependency inversion would be more obvious to see if we had not first created **TimerTask**

- After dependency inversion (without TimerTask):

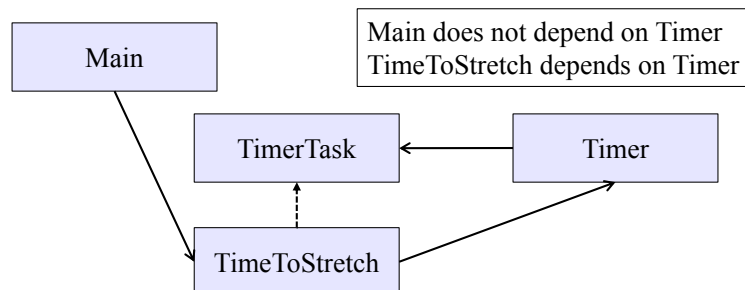

## Main (version 3)

```
TimeToStretch tts = new TimeToStretch();
```

```
tts.start();
```

- Uses a callback in **TimeToStretch** to invert a dependency
- This MDD shows the inversion of the dependency between **Timer** and **TimeToStretch** (compare to version 1)

## Concept Summary (example 1)

**Coupling** – dependency between different parts

- Use coupling only where necessary
- Decouple needlessly coupled components

**Reusability**

- Uncoupled components are more reusable

**Modularity**

- The resulting design is modular because each component does its own functionality (no more, no less)

**Callbacks**

- The concept of passing in a method that will be called later

We have applied the concept of callbacks to decouple needlessly coupled components!

# Example 2

## Design exercise #2

A program to display information about stocks

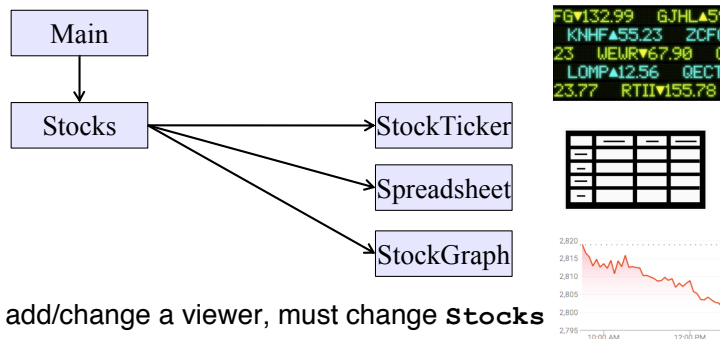

- Stock tickers
- Spreadsheets
- Graphs

Naive design:

- Make a class to represent stock information
- That class updates all views of that information (tickers, graphs, etc.) when it changes

## Module dependency diagram

- Main class gathers information and stores in **Stocks**
- **Stocks** class updates viewers when necessary

Problem: To add/change a viewer, must change **Stocks**  
Better: insulate **stocks** from the details of the viewers

## Weaken the coupling

What should **stocks** class know about viewers?

- Only needs an **update** method to call with changed data
- Old way:

```
void updateViewers () {  
    ticker.update(newPrice);  
    spreadsheet.update(newPrice);  
    graph.update(newPrice);  
    // Edit this method to  
    // add a new viewer. ☹  
}
```

## Weaken the coupling

What should `Stocks` class know about viewers?

- Only needs an `update` method to call with changed data
- New way: The “observer pattern”

```
interface PriceObserver {
    void update(PriceInfo pi);
}

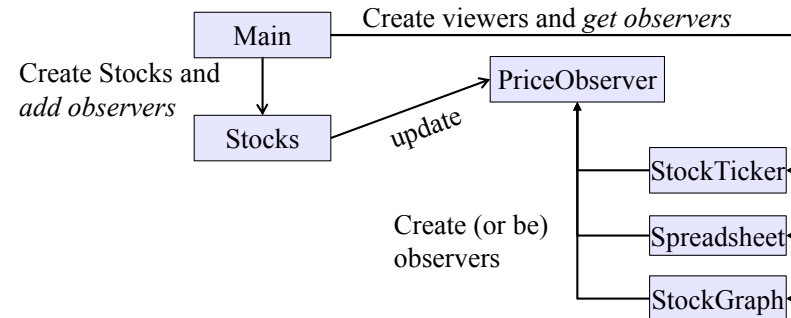

class Stocks {
    private List<PriceObserver> observers;
    void addObserver(PriceObserver pi) {
        observers.add(pi);
    }
    void notifyObserver(PriceInfo i) {
        for (PriceObserver obs : observers)
            obs.update(i);
    }
    ...
}
```

Register a callback

Execute callbacks

## The observer pattern

- `Stocks` not responsible for viewer creation
- `Main` passes viewers to `Stocks` as *observers*
- `Stocks` keeps list of `PriceObservers`, notifies them of changes

- Issue: `update` method must pass enough information to (unknown) viewers

## A different design: pull versus push

- The Observer pattern implements *push* functionality
- A *pull* model: give viewers access to `Stocks`, let them extract the data they need

“Push” versus “pull” efficiency can depend on frequency of operations  
(Also possible to use both patterns simultaneously.)

## Concept Summary (example 2)

**Coupling** – dependency between different parts

- We decoupled `Stocks` from the viewer components

**Reusability**

- Uncoupled components are more reusable

**Modularity**

- The resulting design is modular because each component does its own functionality (no more, no less)

**Extensibility** – ability to easily add new features

- (different from concept of extending a class to make subclass)
- The application is more extensible now because we could add more viewers without modifying `Stocks`

We used the [Observer Pattern](#) to improve the `Stocks` application!

# Example 3

## Another example of Observer pattern

```
// Represents a sign-up sheet of students
public class SignupSheet extends Observable {
    private List<String> students
        = new ArrayList<String>();
    public void addStudent(String student) {
        students.add(student);
        setChanged();
        notifyObservers();
    }
    public int size() {
        return students.size();
    }
    ...
}
```

java.util.  
Observable

SignupSheet inherits many methods including:  
void addObserver(Observer o)  
protected void setChanged()  
void notifyObservers()

## An Observer

```
public class SignupObserver implements Observer {
    // called whenever observed object changes
    // and observers are notified
    public void update(Observable o, Object arg) {
        System.out.println("Signup count: "
            + ((SignupSheet)o).size());
    }
}
```

java.util.  
Observer

Not relevant to us

cast because  
Observable is  
not generic ☹

## Registering an observer

```
SignupSheet s = new SignupSheet();
s.addStudent("billg");
// nothing visible happens
s.addObserver(new SignupObserver());
s.addStudent("torvalds");
// now text appears: "Signup count: 2"
```

Java's "Listeners" (particularly in GUI classes) are examples of the Observer pattern

(Feel free to use the Java observer classes in your designs – if they are a good fit – but you don't have to use them)

## User interfaces: appearance vs. content

It is easy to tangle up *appearance* and *content*

- Particularly when supporting direct manipulation (e.g., dragging line endpoints in a drawing program)
- Another example: program state stored in widgets in dialog boxes

Neither can be understood easily or changed easily

This destroys modularity and reusability

- Over time, it leads to bizarre hacks and huge complexity
- Code must be discarded

Callbacks, listeners, and other patterns can help
