What Is A Design Pattern

• A standard solution to a common programming problem
• A technique for making code more flexible
• Shorthand for describing program design and how program components are connected
Creational Patterns

• Problem: Constructors in Java are not flexible
  o Always return a fresh new object, never reuse one
  o Can’t return a subtype of the class they belong to

• Solution: Creational patterns!
  o Sharing
    • Singleton
    • Interning
    • Flyweight
  o Factories
    • Factory method
    • Factory object
  o Builder
Creational Patterns: Sharing

- The old way: Java constructors always create a new object
- **Singleton**: only one object exists at runtime
- **Interning**: only one object with a particular (abstract) value exists at runtime
- **Flyweight**: separate intrinsic and extrinsic state, represents them separately, and interns the intrinsic state
Singleton

- For a class where only one object of that class can ever exist

- “Ensure a class has only one instance, and provide a global point of access to it.” -- GoF, *Design Patterns*

- Two possible implementations
  - Eager initialization: creates the instance when the class is loaded to guarantee availability
  - Lazy initialization: only creates the instance once it’s needed to avoid unnecessary creation
Singleton

• Eager initialization

```java
public class Bank {
    private static Bank INSTANCE = new Bank();

    // private constructor
    private Bank() { ... }

    // factory method
    public static Bank getInstance() {
        return INSTANCE;
    }
}
```

Bank b = new Bank();
Bank b = Bank.getInstance();
Singleton

- Lazy initialization

```java
public class Bank {
    private static Bank INSTANCE;

    // private constructor
    private Bank() { … }

    // factory method
    public static Bank getInstance() {
        if (INSTANCE == null) {
            INSTANCE = new Bank();
        }
        return INSTANCE;
    }
}

Bank b = new Bank();
Bank b = Bank.getInstance();
```
Singleton

• Would you prefer eager or lazy instantiation for an HTTPRequest class?
  o handles authentication
  o definitely needed for any HTTP transaction

• Would you prefer eager or lazy instantiation for a Comparator class?
  o compares objects
  o may or may not be used at runtime
Singleton

```java
public class HttpRequest {
    private static class HttpRequestHolder {
        public static final HttpRequest INSTANCE =
            new HttpRequest();
    }

    /* Singleton – Don’t instantiate */
    private HttpRequest() {
    }

    public static HttpRequest getInstance() {
        return HttpRequestHolder.INSTANCE;
    }
}
```
public class LengthComparator implements Comparator<String> {
    private int compare(String s1, String s2) {
        return s1.length() - s2.length();
    }

    /* Singleton – Don’t instantiate */
    private LengthComparator() { … }
    private static LengthComparator comp = null;

    public static LengthComparator getInstance() {
        if (comp == null) {
            comp = new LengthComparator();
        }
        return comp;
    }
}
Interning

• Similar to Singleton, except instead of just having one object per class, there’s one object per \textit{abstract value} of the class
• Saves memory by compacting multiple copies
public class Point {
    private int x, y;

    public Point(int x, int y) {
        this.x = x;
        this.y = y;
    }
    public int getX() { return x; }
    public int getY() { return y; }

    @Override
    public String toString() {
        return "(" + x + "," + y + ")";
    }
}
Interning

public class Point {
    private static Map<String, Point> instances =
        new HashMap<String, Point>();

    public static Point getInstance(int x, int y) {
        String key = x + "," + y;
        if (!instances.containsKey(key))
            instances.put(key, new Point(x, y));
        return instances.get(key);
    }

    private final int x, y; // immutable
    private Point(int x, int y) {...}
}

Requires the class being interned to be immutable. Why?
Interning

• What if Points were represented in polar coordinates?
• What further checks are necessary to make sure these kinds of Points are interned correctly?
Interning

```java
public class Point {
    private static Map<String, Point> instances =
        new HashMap<String, Point>();

    public static Point getInstance(double r, double theta) {
        double normalizedTheta = normalize(theta);
        String key = r + "\," + normalizedTheta;
        if (!instances.containsKey(key))
            instances.put(key,
                new Point(r, normalizedTheta));
        return instances.get(key);
    }

    private final double r, theta; // immutable
    private Point(double r, double theta) {...}
}

Why do we need to normalize?
```
Summary: Sharing Patterns

• The old way: Java constructors always create a new object

• **Singleton**: only one object exists at runtime

• **Interning**: only one object with a particular (abstract) value exists at runtime

• **Flyweight**: separate intrinsic and extrinsic state, represents them separately, and interns the intrinsic state
Factories

• Suppose we want a constructor for Set that takes a list as a parameter, and produces a TreeSet if the list is sorted, and a HashSet otherwise.
• Is this possible?
Factories

• Factories solve the problem that Java constructors cannot return a subtype of the class they belong to

• Two options:
  o Factory method
    • A method that creates and returns objects
    • Method defines the interface for creating an object, but defers instantiation to subclasses
  o Factory object
    • Abstract superclass defines what can be customized
    • Concrete subclass does the customization, returns appropriate subclass
public static Set produceSet(List list) {
    if (isSorted(list)) {
        return new TreeSet(list);
    } else {
        return new HashSet(list);
    }
}
Factory Object

```java
interface SetFactory {
    Set getSet();
}

class HashSetFactory implements SetFactory {
    public Set getSet() {
        return new HashSet();
    }
}
```
Builder

• The class has an inner class `Builder` and is created using the `Builder` instead of the constructor.
• The `Builder` takes optional parameters via setter methods (e.g., `setX()`, `setY()`, etc.).
• When the client is done supplying parameters, she calls `build()` on the `Builder`, finalizing the builder and returning an instance of the object desired.
• Useful when you have many constructor parameters
  - It is hard to remember which order they should all go in.
• Easily allows for optional parameters
  - If you have n optional parameters, you need $2^n$ constructors, but only one builder.
public class NutritionFacts {
  private final int servingSize, servings; // required
  private final int calories, fat, sodium; // optional

  // all the constructors!
  public NutritionFacts(int srvSize, int servings) {
    this(srvSize, servings, 0); }
  public NutritionFacts(int srvSize, int servings, int cal) {
    this(srvSize, servings, cal, 0); }
  public NutritionFacts(int srvSize, int servings, int cal, int fat) {
    this(srvSize, servings, cal, fat, 0); }
  ...
  public NutritionFacts(int srvSize, int servings, int calories, int fat, int sodium) {
    this.servingSize = srvSize;
    this.servings = servings;
    this.calories = calories;
    this.fat = fat;
    this.sodium = sodium;
  }
}
public class NutritionFacts {
    private final int servingSize, servings, calories, fat, sodium;

    // inner builder class
    public static class Builder {
        private int servingSize, servings; // required
        private int calories = 0, fat = 0, sodium = 0; // optional

        public Builder(int servingSize, int servings) {
            this.servingSize = servingSize;
            this.servings = servings;
        }

        public Builder calories(int val) { calories = val; return this; }
        public Builder fat(int val) { fat = val; return this; }
        public Builder sodium(int val) { sodium = val; return this; }
        public NutritionFacts build() { return new NutritionFacts(this); }
    }

    // only one constructor 😊
    public NutritionFacts(Builder builder) {
        this.servingSize = builder.servingSize;
        this.servings = builder.servings;
        this.calories = builder.calories;
        this.fat = builder.fat;
        this.sodium = builder.sodium;
    }
}
public class NutritionFacts {
    private final int servingSize, servings, calories, fat, sodium;

    // inner builder class
    public static class Builder {
        private int servingSize, servings; // required
        private int calories = 0, fat = 0, sodium = 0; // optional

        public Builder(int servingSize, int servings) {
            this.servingSize = servingSize;
            this.servings = servings;
        }

        public Builder calories(int val) { calories = val; return this; }
        public Builder fat(int val) { fat = val; return this; }
        public Builder sodium(int val) { sodium = val; return this; }

        public NutritionFacts build() { return new NutritionFacts(this); }
    }

    // only one constructor 😊
    public NutritionFacts(Builder builder) {
        this.servingSize = builder.servingSize;
        this.servings = builder.servings;
        this.calories = builder.calories;
        this.fat = builder.fat;
        this.sodium = builder.sodium;
    }
}
Structural Patterns

- Problem: Sometimes difficult to realize relationships between entities
  - Important for code readability

- Solution: Structural patterns!
  - We’re just going to talk about wrappers, which translate between incompatible interfaces

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Functionality</th>
<th>Interface</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adapter</td>
<td>same</td>
<td>different</td>
<td>modify the interface</td>
</tr>
<tr>
<td>Decorator</td>
<td>different</td>
<td>same</td>
<td>extend behavior</td>
</tr>
<tr>
<td>Proxy</td>
<td>same*</td>
<td>same</td>
<td>restrict access</td>
</tr>
</tbody>
</table>

*from client's perspective
Adapter

• Changes an interface without changing functionality
  o Rename a method
  o Convert units

• Examples:
  o Angles passed in using radians vs. degrees
  o Bytes vs. strings
Decorator

- Adds functionality without changing the interface
  - Add caching
- Adds to existing methods to do something additional while still preserving the previous spec
  - Add logging
- Decorators can remove functionality without changing the interface
  - UnmodifiableList with add() and put()
Proxy

• Wraps the class while maintaining the same interface and functionality
• Integer vs. int, Boolean vs. boolean
• Controls access to other objects
  o Communication: manage network details when using a remote object
  o Security: permit access only if proper credentials
  o Creation: object might not yet exist because creation is expensive
Activity

- What pattern would you use to...
  - add a scroll bar to an existing window object in Swing
  - We have an existing object that controls a communications channel. We would like to provide the same interface to clients but transmit and receive encrypted data over the existing channel.
Activity

- What pattern would you use to...
  - add a scroll bar to an existing window object in Swing
    - Decorator
  - We have an existing object that controls a communications channel. We would like to provide the same interface to clients but transmit and receive encrypted data over the existing channel.
    - Proxy

Adapted, Builder, Decorator, Factory, Flyweight, Intern, Model-View-Controller (MVC), Proxy, Singleton, Visitor, Wrapper
