Data Abstraction: Abstract Data Types (ADTs)
Administrivia

- Effective Java 3\textsuperscript{rd} edition readings added to calendar
  - Either 2\textsuperscript{nd} or 3\textsuperscript{rd} edition should be fine – pick one
    (haven’t had a chance to check all details yet, but everything seems fine so far)
- HW4 pushed to repos this afternoon
  - Do a git pull before any commit/push, but if you get a merge conflict, do a pull then add/commit as usual and accept any merge conflict defaults
  - Take a look at hw4 before sections tomorrow
- Lectures are a little behind sections, but should catch up by Friday
- HW1 regrades enabled this afternoon
- Oracle released new JDK updates this week – doesn’t seem urgent to upgrade, but might as well…
  - If you do, install a new full JDK
Outline

This lecture:
1. What is an Abstract Data Type (ADT)?
2. How to specify an ADT?
3. Design methodology for ADTs

Very related next lectures:
• Representation invariants
• Abstraction functions

Two distinct, complementary ideas for reasoning about ADTs
Procedural and data abstractions

**Procedural** abstraction:
- Abstract from details of procedures (e.g., methods)
- Specification is the abstraction
  - Abstraction is the specification
- Satisfy the specification with an implementation

**Data** abstraction:
- Abstract from details of data representation
- Also a specification mechanism
  - A way of thinking about programs and design
- Standard terminology: Abstract Data Type, or ADT
Why we need Data Abstractions (ADTs)

Organizing and manipulating data is pervasive
- Inventing and describing algorithms is less common

Start your design by designing data structures
- How will relevant data be organized
- What operations will be permitted on the data by clients
- Cf. CSE 332

Potential problems with choosing a data abstraction:
- Decisions about data structures often made too early
- Duplication of effort in creating derived data
- Very hard to change key data structures (modularity!)
Bad programmers worry about the code. Good programmers worry about data structures and their relationships.

-- Linus Torvalds

Show me your flowcharts and conceal your tables, and I shall continue to be mystified. Show me your tables, and I won’t usually need your flowcharts; they’ll be obvious.

-- Fred Brooks
An ADT is a set of operations

- ADT abstracts from the *organization* to *meaning* of data
- ADT abstracts from *structure* to *use*
- Representation should not matter to the client
  - So hide it from the client

```java
class RightTriangle {
    float base, altitude;
}
```

Instead, think of a type as a *set of operations*

- `create`, `getBase`, `getAltitude`, `getBottomAngle`, ...

Force clients to use operations to access data
Are these classes the same?

class Point {
    public float x;
    public float y;
}

class Point {
    public float r;
    public float theta;
}

Different: cannot replace one with the other in a program

Same: both classes implement the concept “2-d point”

Goal of ADT methodology is to express the sameness:
    – Clients depend only on the concept “2-d point”
Benefits of ADTs

If clients “respect” or “are forced to respect” data abstractions…
  – For example, “it’s a 2-D point with these operations…”

• Can delay decisions on how ADT is implemented
• Can fix bugs by changing how ADT is implemented
• Can change algorithms
  – For performance
  – In general or in specialized situations
• ...

We talk about an “abstraction barrier”
  – A good thing to have and not cross (also known as violate)
class Point {
    // A 2-d point exists in the plane, ...
    public float x();
    public float y();
    public float r();
    public float theta();

    // ... can be created, ...
    public Point(); // new point at (0,0)
    public Point centroid(Set<Point> points);

    // ... can be moved, ...
    public void translate(float delta_x, float delta_y);
    public void scaleAndRotate(float delta_r, float delta_theta);
}

Observers
Creators/Producers
Mutators
Abstract data type = objects + operations

- Implementation is hidden
- The only operations on objects of the type are those provided by the abstraction
Specifying a data abstraction

- A *collection* of procedural abstractions
  - *Not* a collection of procedures

- An *abstract state*
  - Not the (concrete) representation in terms of fields, objects, …
  - “Does not exist” but used to specify the operations
  - Concrete state, not part of the specification, implements the abstract state
    - More in upcoming lecture

- Each operation described in terms of “creating”, “observing”, “producing”, or “mutating”
  - No operations other than those in the specification
Specifying an ADT

<table>
<thead>
<tr>
<th>Immutable</th>
<th>Mutable</th>

<td>5. producers <em>(rare)</em></td>
</tr>
<tr>
<td>6. mutators</td>
<td>6. mutators</td>
</tr>
</tbody>
</table>

- **Creators**: return new ADT values (e.g., Java constructors)
- **Producers**: ADT operations that return new ADT values
- **Mutators**: Modify a value of an ADT
- **Observers**: Return information about an ADT
To implement a data abstraction (e.g., with a Java class):
- See next two lectures
- This lecture is just about specifying an ADT
- *Nothing* about the concrete representation appears in the specification
Poly, an immutable datatype: overview

/**
 * A Poly is an immutable polynomial with
 * integer coefficients. A typical Poly is
 * \[ c_0 + c_1 x + c_2 x^2 + \ldots \]
 ***/

class Poly {

Overview:

- State whether mutable or immutable
- Define an abstract model for use in operation specifications
  - Difficult and vital!
  - Appeal to math if appropriate
  - Give an example (reuse it in operation definitions)
- State in specifications is abstract, not concrete
Poly: creators

// effects: makes a new Poly = 0
public Poly()

// effects: makes a new Poly = cx^n
// throws: NegExponent if n < 0
public Poly(int c, int n)

Creators
- New object, not part of pre-state: in effects, not modifies
- Overloading: distinguish procedures of same name by parameters (Example: two Poly constructors)

Footnote: slides omit full JavaDoc comments to save space; style might not be perfect either – focus on main ideas
Poly: observers

// returns: the degree of this,
// i.e., the largest exponent with a
// non-zero coefficient.
// Returns 0 if this = 0.
public int degree()

// returns: the coefficient of the term
// of this whose exponent is d
// throws: NegExponent if d < 0
public int coeff(int d)
Notes on observers

Observers
- Used to obtain information about objects of the type
- Return values of other types
- Never modify the abstract value
- Specification uses the abstraction from the overview

this
- The particular Poly object being accessed
- Target of the invocation
- Also known as the receiver

Poly x = new Poly(4, 3);
int c = x.coeff(3);
System.out.println(c);  // prints 4
Poly: producers

// returns: this + q (as a Poly)
public Poly add(Poly q)

// returns: the Poly equal to this * q
public Poly mul(Poly q)

// returns: -this
public Poly negate()
Notes on producers

- Operations on a type that create other objects of the type

- Common in immutable types like `java.lang.String`
  - `String substring(int offset, int len)`

- No side effects
  - Cannot change the abstract value of existing objects
IntSet, a mutable datatype: overview and creator

// Overview: An IntSet is a mutable, unbounded set of integers. A typical IntSet is \{ x_1, \ldots, x_n \}.

class IntSet {

// effects: makes a new IntSet = {}
public IntSet()
IntSet: observers

// returns: true if and only if x ∈ this
public boolean contains(int x)

// returns: the cardinality of this
public int size()

// returns: some element of this
// throws: EmptyException when size()==0
public int choose()
IntSet: mutators

// modifies: this
// effects: \( \text{this}_{post} = \text{this}_{pre} \cup \{x\} \)
public void add(int x)

// modifies: this
// effects: \( \text{this}_{post} = \text{this}_{pre} - \{x\} \)
public void remove(int x)
Notes on mutators

• Operations that modify an element of the type

• Rarely modify anything (available to clients) other than this
  – List this in modifies clause (if appropriate)

• Typically have no return value
  – “Do one thing and do it well”
  – (Sometimes return “old” value that was replaced)

• Mutable ADTs may have producers too, but that is less common
