Spring 2020
Subtypes and Subclasses
What is subtyping?

Sometimes “every B is an A”
  – examples in a library database:
    • every book is a library holding
    • every CD is a library holding

For subtyping, “B is a subtype of A” means:
  – “every object that satisfies the rules for a B also satisfies the rules for an A”
  – (B is a strengthening of A)

Goal: code written using A's spec operates correctly if given a B
  – plus: clarify design, share tests, (sometimes) share code
Subtypes are substitutable

Subtypes are substitutable for supertypes

- Liskov substitution principle
- instances of subtype won't surprise client by failing to satisfy the supertype's specification
- instances of subtype won't surprise client with more expectations than the supertype's specification

We say B is a (true) subtype of A if B has a stronger specification than A

- (or is equally strong)
- this is not the same as a Java subtype (e.g. subclass)
- Java subclasses that are not true subtypes: confusing & dangerous
  - but unfortunately common 😞
  - Java allows casting sub- to supertypes assuming true subtypes
Subtyping vs. subclassing

Substitution (subtype) is a matter of specifications
- B is a subtype of A iff an object of B can masquerade as an object of A in any context
- B is a subtype if its spec is is a strengthening of A’s spec

Inheritance (subclass) is a matter of implementations
- factor out repeated code
- to create a new class, write only the differences

Java purposely merges these notions for classes:
- every subclass is a Java subtype
- but not necessarily a true subtype
- (though Java casting rules assume true subtypes)
Inheritance makes adding functionality easy

Suppose we run a web store with a class for products…

class Product {
    private String title;
    private String description;
    private int price; // in cents
    public int getPrice() {
        return price;
    }
    public int getTax() {
        return (int)(getPrice() * 0.086);
    }
    ...
}

... and we need a class for products that are on sale
class SaleProduct {
    private String title;
    private String description;
    private int price; // in cents
    private float factor;
    public int getPrice() {
        return (int)(price*factor);
    }
    public int getTax() {
        return (int)(getPrice() * 0.086);
    }
    ...
}

Not a good choice. — Why? (hint: properties of high quality code)
Inheritance makes small extensions small

Better:

class SaleProduct extends Product {
    private float factor;
    public int getPrice() {
        return (int)(super.getPrice()*factor);
    }
}
Benefits of subclassing & inheritance

• Don’t repeat unchanged fields and methods
  – in implementation:
    • simpler maintenance: fix bugs once (changeability)
  – in specification:
    • clients who understand the superclass specification need only study novel parts of the subclass (readability)
    • differences not buried under mass of similarities
  – modularity: can ignore private fields and methods of superclass (if properly designed)

• Ability to substitute new implementations (modularity)
  – no client code changes required to use new subclasses
Subclassing can be misused

• Poor design can produce subclasses that depend on many implementation details of superclasses
  – super- and sub-classes are often highly interdependent (i.e., tightly coupled)
• Changes in superclasses can break subclasses
  – “fragile base class problem”
• Subtyping and implementation inheritance are orthogonal!
  – subclassing gives you both
  – sometimes you want just one. instead use:
    • interfaces: subtyping without inheritance
    • composition: use implementation without subtyping
      – can seem less convenient, but often better long-term
(NON-)EXAMPLES
Is every square a rectangle?

interface Rectangle {  
  // effects: fits shape to given size: 
  //     this.width = w, this.height = h 
  void setSize(int w, int h);
} 

interface Square extends Rectangle {...}

Which is the best option for Square’s setSize specification?

1. // effects: sets all edges to given size 
   void setSize(int edgeLength);

2. // requires: w = h 
   // effects: fits shape to given size 
   void setSize(int w, int h);

3. // effects: sets this.width and this.height to w 
   void setSize(int w, int h);

4. // effects: fits shape to given size 
   // throws BadSizeException if w != h 
   void setSize(int w, int h) throws BadSizeException;
Square is not a (true subtype of) Rectangle:
- Rectangles are expected to have a width and height that can be mutated independently
- Squares violate that expectation, could surprise client

Rectangle is not a (true subtype of) Square:
- Squares are expected to have equal widths and heights
- Rectangles violate that expectation, could surprise client

Subtyping is not always intuitive
- but it forces clear thinking and prevents errors

Solutions:
- make them unrelated (or siblings)
- make them immutable!
  - recovers elementary-school intuition
Inappropriate subtyping in the JDK

class Hashtable {
    public void put(Object key, Object value){...}
    public Object get(Object key){...}
}

// Keys and values are strings.
class Properties extends Hashtable {
    public void setProperty(String key, String val) {
        put(key,val);
    }
    public String getProperty(String key) {
        return (String)get(key);
    }
}

Properties p = new Properties();
Hashtable tbl = p;
tbl.put("One", 1);
p.getProperty("One"); // crash!
Violation of rep invariant

Properties class has a simple rep invariant:
- keys and values are Strings

But client can treat Properties as a Hashtable
- can put in arbitrary content, break rep invariant

From Javadoc:

Because Properties inherits from Hashtable, the put and putAll methods can be applied to a Properties object. ... If the store or save method is called on a "compromised" Properties object that contains a non-String key or value, the call will fail.
Solution: Composition

class Properties {
    private Hashtable hashtable;

    public void setProperty(String key, String value) {
        hashtable.put(key, value);
    }

    public String getProperty(String key) {
        return (String) hashtable.get(key);
    }

    ...
}

You do not need to be a subclass of every class whose code you want to use!

Now, there are no get and put methods on Properties. (Best choice.)
SUBTYPES VS SUBCLASSES
Substitution principle for classes

If B is a subtype of A, then a B can always be substituted for an A.

Any property guaranteed by A must be guaranteed by B.
- Anything provable about an A is provable about a B.
- If an instance of subtype is treated purely as supertype (only supertype methods/fields used), then the result should be consistent with an object of the supertype being manipulated.

B is permitted to strengthen properties and add properties.
- An overriding method must have a stronger (or equal) spec.
- Fine to add new methods (that preserve invariants).

B is not permitted to weaken the spec.
- No overriding method with a weaker spec.
- No method removal.
Substitution principle for methods

Constraints on methods

– For each supertype method, subtype must have such a method
  • (could be inherited or overridden)

Each overridden method must *strengthen* (or match) the spec:

– ask nothing extra of client (“weaker precondition”)
  • *requires* clause is at most as strict as in supertype’s method
– guarantee at least as much (“stronger postcondition”)
  • *effects* clause is at least as strict as in the supertype method
  • no new entries in *modifies* clause
  • promise more (or the same) in *returns* & *throws* clauses
    – cannot change return values or switch between return and throws
Spec strengthening: argument/result types

For method inputs:
- argument types in A’s foo could be replaced with supertypes in B’s foo
- places no extra demand on the clients
- **but** Java does not have such overriding
  - these are different methods in Java!

For method outputs:
- result type of A’s foo may be replaced by a subtype in B’s foo
- no new exceptions (for values in the domain)
- existing exceptions can be replaced with subtypes (none of this violates what client can rely on)
Java subtyping

- Java types:
  - defined by classes, interfaces, primitives

- Java subtyping stems from `B extends A` and `B implements A` declarations

- In a Java subtype, each corresponding method has:
  - same argument types
    - if different, then *overloading* — unrelated methods
  - compatible return types
  - no additional declared exceptions
Java subtyping guarantees

A variable’s run-time type (i.e., the class of its run-time value) is a Java subtype of its declared type

```java
Object o = new Date(); // OK
Date d = new Object(); // compile-time error
```

If a variable of declared (compile-time) type T1 holds a reference to an object of actual (runtime) type T2, then T2 must be a Java subtype of T1

Corollaries:
- objects always have implementations of the methods specified by their declared type
- if all subtypes are true subtypes, then all objects meet the specification of their declared type

Rules out a huge class of bugs
Java subtyping non-guarantees

Java subtyping does **not** guarantee that overridden methods
- have smaller requires
- have smaller modifies
- have stronger postconditions
  - Java only checks the *return type* not the postcondition
  - could compute a completely different function
- have stronger effects
- have stronger throws (& only for the same cases as before)
- have no new unchecked exceptions
DESIGNING FOR INHERITANCE
Inheritance can break encapsulation

```java
public class InstrumentedHashSet<E> extends HashSet<E> {
    private int addCount = 0; // count # insertions
    public InstrumentedHashSet(Collection<? extends E> c) {
        super(c);
    }
    public boolean add(E o) {
        addCount++;
        return super.add(o);
    }
    public boolean addAll(Collection<? extends E> c) {
        addCount += c.size();
        return super.addAll(c);
    }
    public int getAddCount() { return addCount; }
}
```
What does this code print?

```java
InstrumentedHashSet<String> s = new InstrumentedHashSet<String>();
System.out.println(s.getAddCount());  // 0
s.addAll(Arrays.asList("CSE", "331"));
System.out.println(s.getAddCount());  // 4?!}
```

- **Answer** depends on implementation of `addAll` in `HashSet`
  - different implementations may behave differently!
  - if `HashSet`’s `addAll` calls `add`, then double-counting
- **AbstractCollection**’s `addAll` specification:
  - “adds all elements in the specified collection to this collection.”
  - does not specify whether it calls `add`
- **Lesson**: subclassing typically requires designing for inheritance
  - self-calls is not the only example… (more in future lectures)
Solutions

1. Change spec of `HashSet`
   - indicate all self-calls
   - less flexibility for implementers

2. Avoid spec ambiguity by avoiding self-calls
   a) “re-implement” methods such as `addAll`
      • more work
   b) use composition not inheritance
      • no longer a subtype (unless an interface is handy)
      • bad for equality tests, callbacks, etc.
public class InstrumentedHashSet<E> {
    private final HashSet<E> s = new HashSet<E>();
    private int addCount = 0;
    public InstrumentedHashSet(Collection<? extends E> c) {
        this.addAll(c);
    }
    public boolean add(E o) {
        addCount++;
        return s.add(o);
    }
    public boolean addAll(Collection<? extends E> c) {
        addCount += c.size();
        return s.addAll(c);
    }
    public int getAddCount() {
        return addCount;
    }
    // ... and every other method specified by HashSet<E>
Composition (wrappers, delegation)

Implementation *reuse without inheritance*

- Easy to reason about. Self-calls are irrelevant
- Example of a “wrapper” class
- Works around badly-designed / badly-specified classes

Disadvantages (may be worthwhile price to pay):
- does not preserve subtyping
- sometimes tedious to write
- may be hard to apply to equality tests, callbacks, etc.
  - (although we already saw equals is hard for subclasses)
Composition does not preserve subtyping

- **InstrumentedHashSet** is not a **HashSet** anymore
  - so can't easily substitute it

- It may be a true subtype of **HashSet**
  - but Java doesn't know that!
  - Java requires declared relationships
  - not enough just to meet specification

- Interfaces to the rescue
  - can declare that we implement interface **Set**
  - if such an interface exists
Interfaces reintroduce Java subtyping

```java
public class InstrumentedHashSet<E> implements Set<E> {
    private final Set<E> s = new HashSet<E>();
    private int addCount = 0;
    public InstrumentedHashSet(Collection<? extends E> c) {
        this.addAll(c);
    }
    public boolean add(E o) {
        addCount++;
        return s.add(o);
    }
    public boolean addAll(Collection<? extends E> c) {
        addCount += c.size();
        return s.addAll(c);
    }
    public int getAddCount() {
        return addCount;
    }
    // ... and every other method specified by Set<E>
}
```

CSE 331 Spring 2020
Interfaces and abstract classes

Provide *interfaces* for your functionality

– client code to interfaces rather than concrete classes
– allows different implementations later
– facilitates composition, wrapper classes
  • basis of lots of useful, clever techniques
  • we'll see more of these later

Consider also providing helper/template *abstract classes*

– makes writing new implementations much easier
– not necessary to use them to implement an interface, so retain freedom to create radically different implementations
Java library interface/class example

// root interface of collection hierarchy
interface Collection<E>

// skeletal implementation of Collection<E>
abstract class AbstractCollection<E>
    implements Collection<E>

// type of all ordered collections
interface List<E> extends Collection<E>

// skeletal implementation of List<E>
abstract class AbstractList<E>
    extends AbstractCollection<E>
    implements List<E>

// an old friend...
class ArrayList<E> extends AbstractList<E>
Why interfaces instead of classes?

Java design decisions:
- a class has **exactly one** superclass
- a class may implement multiple interfaces
- an interface may extend multiple interfaces

Observation:
- multiple superclasses are difficult to use and to implement
- multiple interfaces, single superclass gets most of the benefit
Pluses and minuses of inheritance

- Inheritance is a powerful way to achieve code reuse

- Inheritance can break encapsulation
  - a subclass may need to depend on unspecified details of the implementation of its superclass
    - e.g., pattern of self-calls
  - subclass may need to evolve in tandem with superclass
    - okay when implementation of both is under control of the same programmer
    - this is tricky to get right and is a source of subtle bugs

- Effective Java:
  - either design for inheritance or else prohibit it
  - favor composition (and interfaces) to inheritance
