Quiz Section 3: ADTs

The next few problems concern the following ADT:

```
/**
 * Represents an immutable collection of integers.
 * Clients can think of a set as a list of integers. However, they can only ask
 * if an integer is present or not. The order of the integers and the number of
 * times an integer appears in the list are inaccessible and do not matter.
public class IntSet {
   * Determines whether n is in the list.
   * @param n the number to look for in the list
   * @returns contains(n, obj), where
         contains(n, nil) := false
         contains(n, m :: L) := true
                                               if m = n
         contains(n, m :: L) := contains(n, L) if m /= n
  public boolean contains(int n);
  /**
   * Creates and returns a new list containing n as well as all of obj.
   * @param n the number to add to the new list.
   * @returns n :: obj
  public IntSet add(int n);
  /** ... */
 public IntSet remove(int n);
```

Answer the following questions about the specification of IntSet.

- a) Explain in your own words what @return n :: obj means. In particular, what is "obj" in this context? Why does this mathematical expression make sense?
- b) Suppose that we have an IntSet T whose abstract state is the list 1::2::3:: nil. What mathematical value is returned by the expression T.add(4) according to the add function specification.
- c) Write a specification for the method remove. It should return a list that all of the numbers in the current list except for the number n, which should no longer be present.
 (Hint: your spec should include a math definition similar to that of contains)

In this problem, we will return to the original specification of IntSet, whose abstract state is a list of elements possibly containing duplicates. We will consider three different concrete representations for it:

For each of the methods shown below, state the concrete representations (1-3) for which it would satisfy the specification of the method in IntSet. In each case, briefly explain why.

```
a) public boolean contains(int n) {
    return Arrays.binarySearch(this.elems, n) >= 0;
}
```

```
b) public boolean contains(int n) {
    for (int i = 0; i < this.elems.length; i++) {
        if (this.elems[i] == n)
            return true;
    }
    return false;
}</pre>
```

```
c) public IntSet add(int n) {
    if (this.contains(n)) {
        return this;
    } else {
        int[] newElems = new int[this.elems.length + 1];
        System.arrayCopy(this.elems, 0, newElems, 1, this.elems.length);
        newElems[0] = n;
        return new IntSetImpl(newElems);
    }
}
```

Consider the following implementation of IntSetImpl, which ensures that the representation invariant is satisfied by sorting the elements in the constructor:

```
public class IntSetImpl implements IntSet {
    // AF: obj = this.elems
    // RI: this.elems is sorted in ascending order
   private int[] elems;
    public IntSetImpl(int[] elems) {
        this.elems = elems;
        // Put the elements in sorted order.
        for (int i = 1; i < elems.length; i++) {</pre>
            int key = elems[i];
            int j = i - 1;
            while (j \ge 0 \&\& elems[j] > key) {
                elems[j + 1] = elems[j];
            }
            elems[j + 1] = key;
        }
    }
```

a) How many test cases are required to get proper coverage of the constructor? Explain your answer and also give a specific set of test inputs that would give proper coverage.
