

CSE332: Data Abstractions
Lecture 15: Topological Sort / Graph Traversals

Ruth Anderson
Winter 2011

Announcements

- **Homework 4** – due Friday Feb 11th at the BEGINNING of lecture
- **Project 2** – Phase B due Tues Feb 15th at 11pm
 - Clarifications posted, check Msg board, email cse332-staff

2/09/2011

2

Today

- Graphs
 - Intro & Definitions
 - Topological Sort
 - Graph Traversals

2/09/2011

Topological Sort

Disclaimer: Do not use for official advising purposes!
(Implies that CSE 332 is a pre-req for CSE 312 – not true)

Problem: Given a DAG $G=(V, E)$, output all the vertices in order such that if no vertex appears before any other vertex that has an edge to it

Example input:

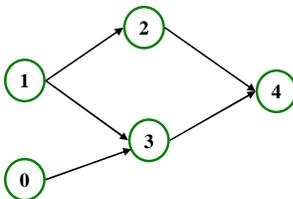

Example output:

142, 126, 143, 311, 331, 332, 312, 341, 351, 333, 440, 352

2/09/2011

4

Valid Topological Sorts:

11/12/2010

Questions and comments

- Why do we perform topological sorts only on DAGs?
- Is there always a unique answer?
- What DAGs have exactly 1 answer?
- Terminology: A DAG represents a **partial order** and a topological sort produces a **total order** that is consistent with it

2/09/2011

6

Questions and comments

- Why do we perform topological sorts only on DAGs?
 - Because a cycle means there is no correct answer
- Is there always a unique answer?
 - No, there can be 1 or more answers; depends on the graph
- What DAGs have exactly 1 answer?
 - Lists
- Terminology: A DAG represents a **partial order** and a topological sort produces a **total order** that is consistent with it

2/09/2011

7

Uses

- Figuring out how to finish your degree
- Computing the order in which to recompute cells in a spreadsheet
- Determining the order to compile files using a Makefile
- In general, taking a dependency graph and coming up with an order of execution

2/09/2011

8

A first algorithm for topological sort

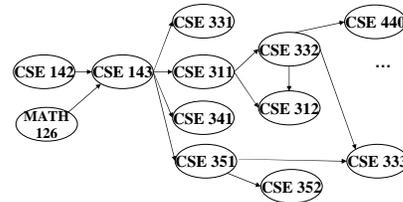

1. Label each vertex with its in-degree
 - Labeling also called marking
 - Think "write in a field in the vertex", though you could also do this with a data structure (e.g., array) on the side
2. While there are vertices not yet output:
 - a) Choose a vertex v with labeled with in-degree of 0
 - b) Output v and "remove it" (conceptually) from the graph
 - c) For each vertex u adjacent to v (i.e. u such that $(v,u) \in \mathcal{E}$), **decrement the in-degree** of u

2/09/2011

9

Example

Output:

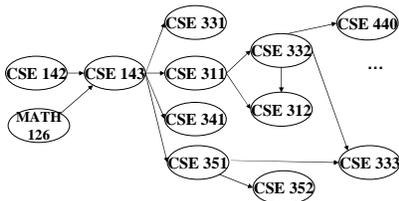

Node:	126	142	143	311	312	331	332	333	341	351	352	440
Removed?												
In-degree:	0	0	2	1	2	1	1	2	1	1	1	1

2/09/2011

10

Example

Output: 126

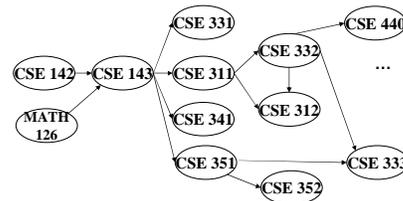

Node:	126	142	143	311	312	331	332	333	341	351	352	440
Removed?	x											
In-degree:	0	0	2	1	2	1	1	2	1	1	1	1
			1									

2/09/2011

11

Example

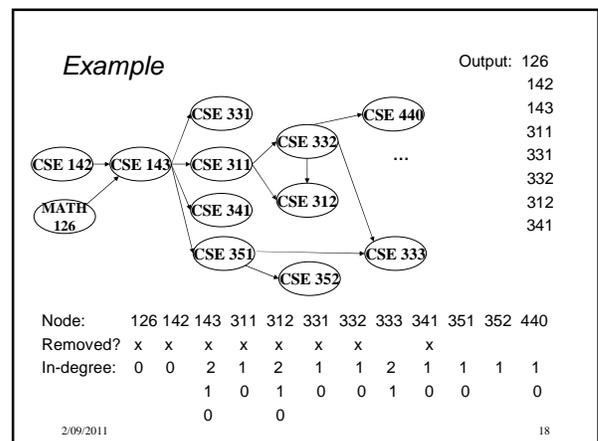

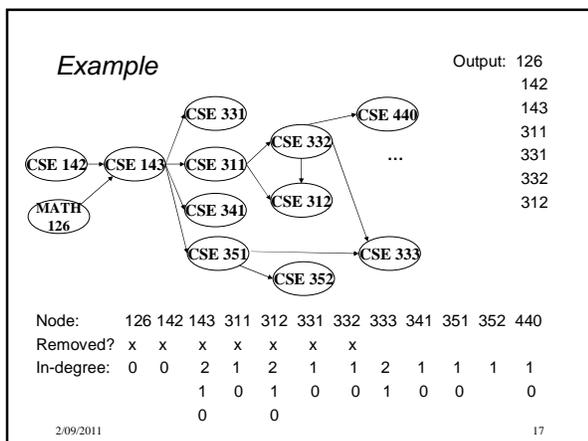

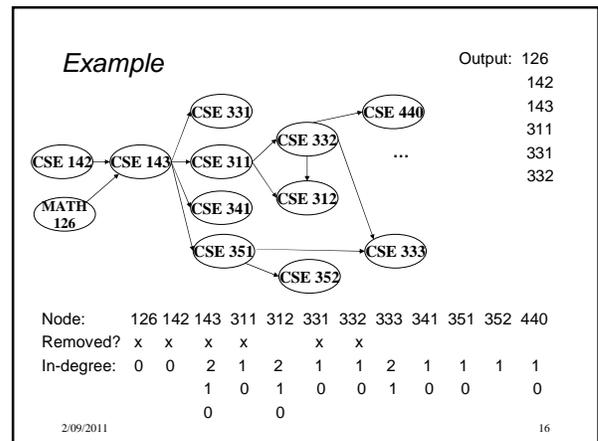

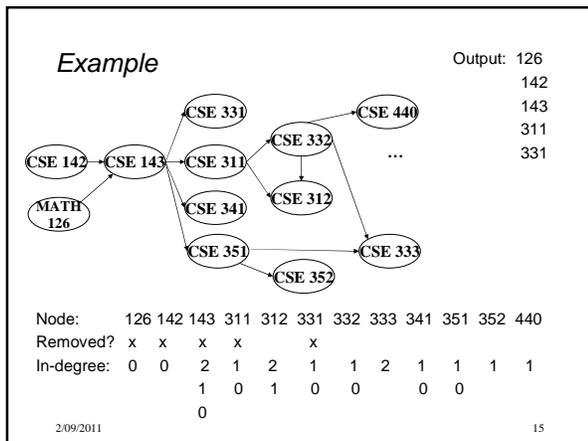

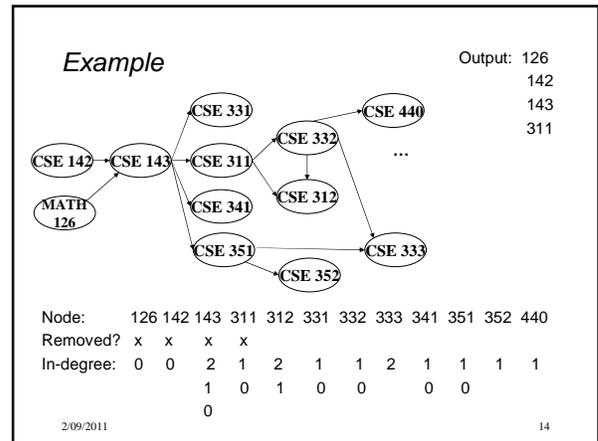

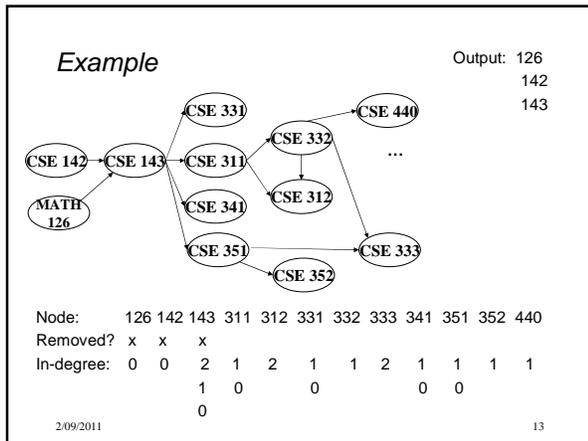

Output: 126
142

Node:	126	142	143	311	312	331	332	333	341	351	352	440
Removed?	x	x										
In-degree:	0	0	2	1	2	1	1	2	1	1	1	1
			1									
			0									

2/09/2011

12

Example

Output: 126
142
143
311
331
332
312
341
351

Node:	126	142	143	311	312	331	332	333	341	351	352	440
Removed?	x	x	x	x	x	x	x		x	x		
In-degree:	0	0	2	1	2	1	1	2	1	1	1	1
			1	0	1	0	0	1	0	0	0	0
			0	0				0				

2/09/2011 19

Example

Output: 126
142
143
311
331
332
312
341
351
333
352
440

Node:	126	142	143	311	312	331	332	333	341	351	352	440
Removed?	x	x	x	x	x	x	x	x	x	x	x	x
In-degree:	0	0	2	1	2	1	1	2	1	1	1	1
			1	0	1	0	0	1	0	0	0	0
			0	0				0				

2/09/2011 20

A couple of things to note

- Needed a vertex with in-degree of 0 to start
 - No cycles
- Ties between vertices with in-degrees of 0 can be broken arbitrarily
 - Potentially many different correct orders

Running time?

```

labelEachVertexWithItsInDegree();
for(ctr=0; ctr < numVertices; ctr++){
  v = findNewVertexOfDegreeZero();
  put v next in output
  for each w adjacent to v
    w.indegree--;
}

```

2/09/2011 22

Running time?

```

labelEachVertexWithItsInDegree();
for(ctr=0; ctr < numVertices; ctr++){
  v = findNewVertexOfDegreeZero();
  put v next in output
  for each w adjacent to v
    w.indegree--;
}

```

- What is the worst-case running time?
 - Initialization $O(|V| + |E|)$
 - Sum of all find-new-vertex $O(|V|^2)$ (because each $O(|V|)$)
 - Sum of all decrements $O(|E|)$ (assuming adjacency list)
 - So total is $O(|V|^2 + |E|)$ – not good for a sparse graph!

2/09/2011 23

Doing better

The trick is to avoid searching for a zero-degree node every time!

- Keep the “pending” zero-degree nodes in a list, stack, queue, box, table, or something
- Order we process them affects output but not correctness or efficiency provided add/remove are both $O(1)$

Using a queue:

1. Label each vertex with its in-degree, enqueue 0-degree nodes
2. While queue is not empty
 - a) $v = \text{dequeue}()$
 - b) Output v and remove it from the graph
 - c) For each vertex u adjacent to v (i.e. u such that $(v,u) \in E$), decrement the in-degree of u , if new degree is 0, enqueue it

2/09/2011 24

Running time?

```
labelAllAndEnqueueZeros();
for(ctr=0; ctr < numVertices; ctr++){
  v = dequeue();
  put v next in output
  for each w adjacent to v {
    w.indegree--;
    if(w.indegree==0) enqueue(w);
  }
}
```

2/09/2011

25

Running time?

```
labelAllAndEnqueueZeros();
for(ctr=0; ctr < numVertices; ctr++){
  v = dequeue();
  put v next in output
  for each w adjacent to v {
    w.indegree--;
    if(w.indegree==0) enqueue(w);
  }
}
```

- What is the worst-case running time?
 - Initialization: $O(|V| + |E|)$
 - Sum of all enqueues and dequeues: $O(|V|)$
 - Sum of all decrements: $O(|E|)$ (assuming adjacency list)
 - So total is $O(|E| + |V|)$ – much better for sparse graph!

2/09/2011

26

Graph Traversals

Next problem: For an arbitrary graph and a starting node v , find all nodes *reachable* (i.e., there exists a path) from v

- Possibly “do something” for each node (an iterator!)
 - E.g. Print to output, set some field, etc.

Related:

- Is an undirected graph connected?
- Is a directed graph weakly / strongly connected?
 - For strongly, need a cycle back to starting node

Basic idea:

- Keep following nodes
- But “mark” nodes after visiting them, so the traversal terminates and processes each reachable node exactly once

2/09/2011

27

Abstract idea

```
traverseGraph(Node start) {
  Set pending = emptySet();
  pending.add(start)
  mark start as visited
  while(pending is not empty) {
    next = pending.remove()
    for each node u adjacent to next
      if(u is not marked) {
        mark u
        pending.add(u)
      }
  }
}
```

2/09/2011

28

Running time and options

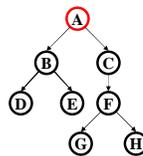

- Assuming add and remove are $O(1)$, entire traversal is $O(|E|)$
- The order we traverse depends entirely on add and remove
 - Popular choice: a stack “depth-first graph search” “DFS”
 - Popular choice: a queue “breadth-first graph search” “BFS”
- DFS and BFS are “big ideas” in computer science
 - Depth: recursively explore one part before going back to the other parts not yet explored
 - Breadth: Explore areas closer to the start node first

2/09/2011

29

Recursive DFS, Example : trees

- A tree is a graph and DFS and BFS are particularly easy to “see”

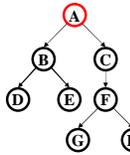

```
DFS(Node start) {
  mark and “process”(e.g. print) start
  for each node u adjacent to start
    if u is not marked
      DFS(u)
}
```

- Order processed: A, B, D, E, C, F, G, H
- Exactly what we called a “pre-order traversal” for trees
 - The marking is because we support arbitrary graphs and we want to process each node exactly once

2/09/2011

30

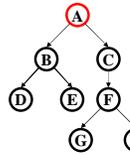

DFS with a stack, Example: trees

```
DFS2(Node start) {
  initialize stack s to hold start
  mark start as visited
  while(s is not empty) {
    next = s.pop() // and "process"
    for each node u adjacent to next
      if(u is not marked)
        mark u and push onto s
  }
}
```

- Order processed: A, C, F, H, G, B, E, D
- A different but perfectly fine traversal

BFS with a queue, Example: trees

```
BFS(Node start) {
  initialize queue q to hold start
  mark start as visited
  while(q is not empty) {
    next = q.dequeue() // and "process"
    for each node u adjacent to next
      if(u is not marked)
        mark u and enqueue onto q
  }
}
```

- Order processed: A, B, C, D, E, F, G, H
- A "level-order" traversal

Comparison

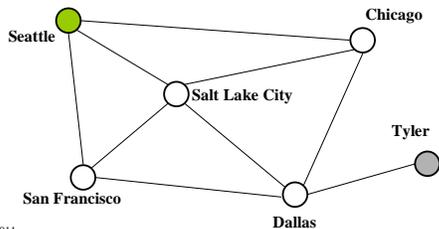

- Breadth-first always finds shortest paths – "optimal solutions"
 - Better for "what is the shortest path from x to y"
- But depth-first can use less space in finding a path
 - If *longest path* in the graph is p and highest out-degree is d then DFS stack never has more than $d \cdot p$ elements
 - But a queue for BFS may hold $O(|V|)$ nodes
- A third approach:
 - *Iterative deepening (IDFS)*: Try DFS but don't allow recursion more than k levels deep. If that fails, increment k and start the entire search over
 - Like BFS, finds shortest paths. Like DFS, less space.

Saving the path

- Our graph traversals can answer the reachability question:
 - "Is there a path from node x to node y?"
- But what if we want to actually output the path?
 - Like getting driving directions rather than just knowing it's possible to get there!
- Easy:
 - Instead of just "marking" a node, store the previous node along the path (when processing u causes us to add v to the search, set $v.path$ field to be u)
 - When you reach the goal, follow $path$ fields back to where you started (and then reverse the answer)
 - If just wanted $path$ length, could put the integer distance at each node instead

Example using BFS

- What is a path from Seattle to Tyler
- Remember marked nodes are not re-enqueued
 - Note shortest paths may not be unique

Example using BFS

- What is a path from Seattle to Tyler
- Remember marked nodes are not re-enqueued
 - Note shortest paths may not be unique
