CSE 332: Data Abstractions

Lecture 23:
Data Races and Memory Reordering
Deadlock
Readers/Writer Locks
Condition Variables

Ruth Anderson
Winter 2013
Announcements

• **Homework 7** – due Friday March 8\textsuperscript{th} at the BEGINNING of lecture!

• **Project 3** – the last programming project!
  – ALL Code - Tues March 12, 2011 11PM - (65\% of overall grade):
  – Writeup - Thursday March 14, 2011, 11PM - (25\% of overall grade)
Outline

Done:
• Programming with locks and critical sections
• Key guidelines and trade-offs

Now: The other basics an informed programmer needs to know
• Why you must avoid data races (memory reorderings)
• Another common error: Deadlock
• Other common facilities useful for shared-memory concurrency
  – Readers/writer locks
  – Condition variables, or, more generally, passive waiting
Motivating memory-model issues

Tricky and surprisingly wrong unsynchronized concurrent code

```java
class C {
    private int x = 0;
    private int y = 0;

    void f() {
        x = 1;
        y = 1;
    }

    void g() {
        int a = y;
        int b = x;
        assert(b >= a);
    }
}
```

First understand why it looks like the assertion cannot fail:

- Easy case: call to `g` ends before any call to `f` starts
- Easy case: at least one call to `f` completes before call to `g` starts
- If calls to `f` and `g` interleave…
Interleavings

There is no interleaving of \( f \) and \( g \) where the assertion fails

- Proof #1: Exhaustively consider all possible orderings of access to shared memory (there are 6)
- Proof #2: If \( ! (b \geq a) \), then \( a == 1 \) and \( b == 0 \).
  But if \( a == 1 \), then \( y = 1 \) happened before \( a = y \).
  Because programs execute in order:
    \( a = y \) happened before \( b = x \) and \( x = 1 \) happened before \( y = 1 \).
  So by transitivity, \( b == 1 \). Contradiction.

Thread 1: \( f \)
- \( x = 1; \)
- \( y = 1; \)

Thread 2: \( g \)
- \( \text{int } a = y; \)
- \( \text{int } b = x; \)
- \( \text{assert}(b \geq a); \)
Wrong

However, the code has a data race

– Two actually
– Recall: data race: unsynchronized read/write or write/write of same location

If code has data races, you cannot reason about it with interleavings!

– That is simply the rules of Java (and C, C++, C#, …)
– (Else would slow down all programs just to “help” programs with data races, and that was deemed a bad engineering trade-off when designing the languages/compilers/hardware)
– So the assertion can fail

Recall Guideline #0: No data races
Why

For performance reasons, the compiler and the hardware often reorder memory operations

- Take a compiler or computer architecture course to learn why

Thread 1: \( f \)

\[
\begin{align*}
  &x = 1; \\
  &y = 1;
\end{align*}
\]

Thread 2: \( g \)

\[
\begin{align*}
  &\text{int }a = y; \\
  &\text{int }b = x; \\
  &\text{assert}(b >= a);
\end{align*}
\]

Of course, you cannot just let them reorder anything they want

- Each thread executes in order after all!
- Consider: \( x=17; \ y=x; \)
**The grand compromise**

The compiler/hardware will never perform a memory reordering that affects the result of a single-threaded program.

The compiler/hardware will never perform a memory reordering that affects the result of a *data-race-free* multi-threaded program.

So: If no interleaving of your program has a data race, then you can *forget about all this reordering nonsense*: the result will be equivalent to some interleaving.

Your job: Avoid data races
Compiler/hardware job: Give illusion of interleaving *if you do your job*
Fixing our example

• Naturally, we can use synchronization to avoid data races
  – Then, indeed, the assertion cannot fail

```java
class C {
    private int x = 0;
    private int y = 0;
    void f() {
        synchronized(this) { x = 1; }
        synchronized(this) { y = 1; }
    }
    void g() {
        int a, b;
        synchronized(this) { a = y; }
        synchronized(this) { b = x; }
        assert (b >= a);
    }
}
```
A second fix

- Java has volatile fields: accesses do not count as data races
- Implementation: slower than regular fields, faster than locks
- Really for experts: avoid them; use standard libraries instead
- And why do you need code like this anyway?

```java
class C {
    private volatile int x = 0;
    private volatile int y = 0;
    void f() {
        x = 1;
        y = 1;
    }
    void g() {
        int a = y;
        int b = x;
        assert(b >= a);
    }
}
```
Code that is wrong

• Here is a more realistic example of code that is wrong
  – No guarantee Thread 2 will ever stop (there’s a data race)
  – But honestly it will “likely work in practice”

```java
class C {
    boolean stop = false;
    void f() {
        while (!stop) {
            // draw a monster
        }
    }
    void g() {
        stop = didUserQuit();
    }
}
```

Thread 1: f()
Thread 2: g()
Outline

Done:
• Programming with locks and critical sections
• Key guidelines and trade-offs

Now: The other basics an informed programmer needs to know

• Why you must avoid data races (memory reorderings)
• Another common error: Deadlock
• Other common facilities useful for shared-memory concurrency
  – Readers/writer locks
  – Condition variables
Motivating Deadlock Issues

Consider a method to transfer money between bank accounts

```java
class BankAccount {
    ...
    synchronized void withdraw(int amt) {...}
    synchronized void deposit(int amt) {...}
    synchronized void transferTo(int amt, BankAccount a) {
        this.withdraw(amt);
        a.deposit(amt);
    }
}
```

Potential problems?
Motivating Deadlock Issues

Consider a method to transfer money between bank accounts

```java
class BankAccount {
    ...  
    synchronized void withdraw(int amt) {...}
    synchronized void deposit(int amt) {...}
    synchronized void transferTo(int amt, BankAccount a) {
        this.withdraw(amt);
        a.deposit(amt);
    }
}
```

Notice during call to `a.deposit`, thread holds two locks
– Need to investigate when this may be a problem
The Deadlock

Suppose $x$ and $y$ are static fields holding accounts

Thread 1: $x\.transferTo\,(1,y)$
- acquire lock for $x$
- do withdraw from $x$
- block on lock for $y$

Thread 2: $y\.transferTo\,(1,x)$
- acquire lock for $y$
- do withdraw from $y$
- block on lock for $x$
Ex: The Dining Philosophers

- 5 philosophers go out to dinner together at an Italian restaurant
- Sit at a round table; one fork per setting
- When the spaghetti comes, each philosopher proceeds to grab their right fork, then their left fork, then eats
- ‘Locking’ for each fork results in a **deadlock**
Deadlock, in general

A deadlock occurs when there are threads $T_1$, $\ldots$, $T_n$ such that:

- For $i=1,\ldots,n-1$, $T_i$ is waiting for a resource held by $T_{i+1}$
- $T_n$ is waiting for a resource held by $T_1$

In other words, there is a cycle of waiting
  - Can formalize as a graph of dependencies with cycles bad

Deadlock avoidance in programming amounts to techniques to ensure a cycle can never arise
Back to our example

Options for deadlock-proof transfer:

1. Make a smaller critical section: `transferTo` not synchronized
   - Exposes intermediate state after `withdraw` before `deposit`
   - May be okay here, but exposes wrong total amount in bank

2. Coarsen lock granularity: one lock for all accounts allowing transfers between them
   - Works, but sacrifices concurrent deposits/withdrawals

3. Give every bank-account a unique number and always acquire locks in the same order
   - *Entire program* should obey this order to avoid cycles
   - Code acquiring only one lock can ignore the order
class BankAccount {
    ...
    private int acctNumber; // must be unique
    void transferTo(int amt, BankAccount a) {
        if(this.acctNumber < a.acctNumber) {
            synchronized(this) {
                synchronized(a) {
                    this.withdraw(amt);
                    a.deposit(amt);
                }
            }
        } else {
            synchronized(a) {
                synchronized(this) {
                    this.withdraw(amt);
                    a.deposit(amt);
                }
            }
        }
    }
}
Another example

From the Java standard library

class StringBuffer {
  private int count;
  private char[] value;
...
  synchronized append(StringBuffer sb) {
    int len = sb.length();
    if(this.count + len > this.value.length)
      this.expand(...);
    sb.getChars(0, len, this.value, this.count);
  }
  synchronized getChars(int x, int y, char[] a, int z) {
    "copy this.value[x..y] into a starting at z"
  }
}
Two problems

Problem #1: Lock for `sb` is not held between calls to `sb.length` and `sb.getChars`
  – So `sb` could get longer
  – Would cause `append` to throw an `ArrayBoundsException`

Problem #2: Deadlock potential if two threads try to `append` in opposite directions, just like in the bank-account first example

Not easy to fix both problems without extra copying:
  – Do not want unique ids on every `StringBuffer`
  – Do not want one lock for all `StringBuffer` objects

Actual Java library: fixed neither (left code as is; changed javadoc)
  – Up to clients to avoid such situations with own protocols
Perspective

• Code like account-transfer and string-buffer append are difficult to deal with for deadlock

• Easier case: different types of objects
  – Can document a fixed order among types
  – Example: “When moving an item from the hashtable to the work queue, never try to acquire the queue lock while holding the hashtable lock”

• Easier case: objects are in an acyclic structure
  – Can use the data structure to determine a fixed order
  – Example: “If holding a tree node’s lock, do not acquire other tree nodes’ locks unless they are children in the tree”
Outline

Done:
• Programming with locks and critical sections
• Key guidelines and trade-offs

Now: The other basics an informed programmer needs to know
• Why you must avoid data races (memory reorderings)
• Another common error: Deadlock
• Other common facilities useful for shared-memory concurrency
  – Readers/writer locks
  – Condition variables
Reading vs. writing

Recall:
– Multiple concurrent reads of same memory: Not a problem
– Multiple concurrent writes of same memory: Problem
– Multiple concurrent read & write of same memory: Problem

So far:
– If concurrent write/write or read/write might occur, use synchronization to ensure one-thread-at-a-time

But this is unnecessarily conservative:
– Could still allow multiple simultaneous readers!
Example

Consider a hashtable with one coarse-grained lock
  – So only one thread can perform operations at a time
  – Won’t allow simultaneous reads, even though it’s ok conceptually

But suppose:
  – There are many simultaneous lookup operations
  – insert operations are very rare
  – It’d be nice to support multiple reads; we’d do lots of waiting otherwise

Note: Important that lookup does not actually mutate shared memory, like a move-to-front list operation would
Readers/writer locks

A new synchronization ADT: The readers/writer lock

- A lock’s states fall into three categories:
  - “not held”
  - “held for writing” by one thread
  - “held for reading” by one or more threads

- **new**: make a new lock, initially “not held”
- **acquire_write**: block if currently “held for reading” or “held for writing”, else make “held for writing”
- **release_write**: make “not held”
- **acquire_read**: block if currently “held for writing”, else make/keep “held for reading” and increment readers count
- **release_read**: decrement readers count, if 0, make “not held”
Pseudocode example (not Java)

```java
class Hashtable<K, V> {
    ...
    // coarse-grained, one lock for table
    RWLock lk = new RWLock();
    V lookup(K key) {
        int bucket = hasher(key);
        lk.acquire_read();
        ...
        read array[bucket] ...
        lk.release_read();
    }

    void insert(K key, V val) {
        int bucket = hasher(key);
        lk.acquire_write();
        ...
        write array[bucket] ...
        lk.release_write();
    }
}
```
Readers/writer lock details

• A readers/writer lock implementation ("not our problem") usually gives priority to writers:
  – Once a writer blocks, no readers arriving later will get the lock before the writer
  – Otherwise an insert could starve
    • That is, it could wait indefinitely because of continuous stream of read requests

• Re-entrant?
  – Mostly an orthogonal issue
  – But some libraries support upgrading from reader to writer

• Why not use readers/writer locks with more fine-grained locking, like on each bucket?
  – Not wrong, but likely not worth it due to low contention
In Java

Java’s `synchronized` statement does not support readers/writer

Instead, library

`java.util.concurrent.locks.ReentrantReadWriteLock`

- Different interface: methods `readLock` and `writeLock` return objects that themselves have `lock` and `unlock` methods

- Does *not* have writer priority or reader-to-writer upgrading
  - Always read the documentation
Outline

Done:
• Programming with locks and critical sections
• Key guidelines and trade-offs

Now: The other basics an informed programmer needs to know

• Why you must avoid data races (memory reorderings)
• Another common error: Deadlock
• Other common facilities useful for shared-memory concurrency
  – Readers/writer locks
  – Condition variables
Motivating Condition Variables: Producers and Consumers

Another means of allowing concurrent access is the condition variable; before we get into that though, let's look at a situation where we'd need one:

- Imagine we have several producer threads and several consumer threads
  - Producers do work, toss their results into a buffer
  - Consumers take results off of buffer as they come and process them
  - Ex: Multi-step computation

![Diagram of producer, buffer, and consumer threads](image-url)
Motivating Condition Variables: Producers and Consumers

• Cooking analogy: Team one peels potatoes, team two takes those and slices them up
  – When a member of team one finishes peeling, they toss the potato into a tub
  – Members of team two pull potatoes out of the tub and dice them up
Motivating Condition Variables: Producers and Consumers

- If the buffer is empty, consumers have to wait for producers to produce more data.
- If buffer gets full, producers have to wait for consumers to consume some data and clear space.
- We’ll need to synchronize access; why?
  - Data race; simultaneous read/write or write/write to back/front.
Motivating Condition Variables

To motivate condition variables, consider the canonical example of a bounded buffer for sharing work among threads.

Bounded buffer: A queue with a fixed size
  – (Unbounded still needs a condition variable, but 1 instead of 2)

For sharing work – think an assembly line:
  – Producer thread(s) do some work and enqueue result objects
  – Consumer thread(s) dequeue objects and do next stage
  – Must synchronize access to the queue
Code, attempt 1

class Buffer<E> {
    E[] array = (E[]) new Object[SIZE];
    // front, back fields, isEmpty, isFull methods
    synchronized void enqueue(E elt) {
        if(isFull())
            ???
        else
            ... add to array and adjust back ...
    }
    synchronized E dequeue()
        if(isEmpty())
            ???
        else
            ... take from array and adjust front ...
    }
}
First attempt

class Buffer<E> {
  E[] array = (E[])new Object[SIZE];
  ...
  // front, back fields, isEmpty, isFull methods
  synchronized void enqueue(E elt) {
    if(isFull())
      ???
    else
      ...
    add to array and adjust back ...
  }
  synchronized E dequeue() {
    if(isEmpty())
      ???
    else
      ...
    take from array and adjust front ...
  }
}

• What to do for ??? One approach; if buffer is full on enqueue, or empty on dequeue, throw an exception
  – Not what we want here; w/ multiple threads taking & giving, these will be common occurrences – should not handle like errors
  – Common, and only temporary; will only be empty/full briefly
  – Instead, we want threads to be pause until it can proceed
Waiting

• **enqueue** to a full buffer should *not* raise an exception
  – Wait until there is room

• **dequeue** from an empty buffer should *not* raise an exception
  – Wait until there is data

Bad approach is to *spin* (wasted work and keep grabbing lock)

```java
void enqueue(E elt) {
    while (true) {
        synchronized (this) {
            if (isFull()) continue;
            ... add to array and adjust back ... return;
        }
    }
} // dequeue similar
```
What we want

- Better would be for a thread to *wait* until it can proceed
  - Be *notified* when it should try again
  - Thread suspended until then; in meantime, other threads run
  - While *waiting*, lock is released; will be re-acquired later by one notified thread
  - Upon being notified, thread just drops in to see what condition it’s condition is in
  - Team two members work on something else until they’re told more potatoes are ready
  - Less contention for lock, and time waiting spent more efficiently
Condition Variables

• Like locks & threads, not something you can implement on your own
  – Language or library gives it to you
• An ADT that supports this: condition variable
  – Informs waiting thread(s) when the condition that causes it/them to wait has varied
• Terminology not completely standard; will mostly stick with Java
Java approach: **not quite right**

class Buffer<E> {
    
    synchronized void enqueue(E elt) {
        if(isFull())
            this.wait(); // releases lock and waits
        add to array and adjust back
        if(buffer was empty)
            this.notify(); // wake somebody up
    }

    synchronized E dequeue() {
        if(isEmpty())
            this.wait(); // releases lock and waits
        take from array and adjust front
        if(buffer was full)
            this.notify(); // wake somebody up
    }
}
Key ideas

- Java weirdness: every object “is” a condition variable (and a lock)
  - other languages/libraries often make them separate

- `wait`:
  - “register” running thread as interested in being woken up
  - then atomically: release the lock and block
  - when execution resumes, `thread again holds the lock`

- `notify`:
  - pick one waiting thread and wake it up
  - no guarantee woken up thread runs next, just that it is no longer blocked on the `condition` – now waiting for the `lock`
  - if no thread is waiting, then do nothing
Bug #1

```java
synchronized void enqueue(E elt) {
    if (isFull())
        this.wait();
    add to array and adjust back
    ...
}
```

Between the time a thread is notified and it re-acquires the lock, the condition can become false again!

Thread 1 (enqueue)

```java
if (isFull())
    this.wait();
add to array
```

Thread 2 (dequeue)

```java
take from array
if (was full)
    this.notify();
```

Thread 3 (enqueue)

```
make full again
```
Bug fix #1

synchronized void enqueue(E elt) {
    while(isFull())
        this.wait();
    ...
}

synchronized E dequeue() {
    while(isEmpty())
        this.wait();
    ...
}

Guideline: *Always* re-check the condition after re-gaining the lock

– If condition still not met, go back to waiting

– In fact, for obscure reasons, Java is technically allowed to notify a thread *spuriously* (i.e., for no reason)
Bug #2

- If multiple threads are waiting, we wake up only one
  - Sure only one can do work *now*, but can’t forget the others!
  - Works for the most part, but what if 2 are waiting to enqueue, and two quick dequeues occur before either gets to go?
  - We’d only notify once; other thread would wait forever

```java
while(isFull())
    this.wait();

Thread 1 (enqueue) Thread 2 (enqueue) Thread 3 (dequeues)
    ...                      ...                  // dequeue #1
    while(isFull())
        this.wait();
        if(buffer was full)
            this.notify();

    ...                      ...                  // dequeue #2
    while(isFull())
        this.wait();
        if(buffer was full)
            this.notify();
```

3/06/2013
**Bug fix #2**

`synchronized void enqueue(E elt) {`  
  
  `if (buffer was empty)`  
  `this.notifyAll(); // wake everybody up`  
`}`

`synchronized E dequeue() {`  
  
  `if (buffer was full)`  
  `this.notifyAll(); // wake everybody up`  
`}

`notifyAll` wakes up all current waiters on the condition variable

Guideline: If in any doubt, use `notifyAll`
  
  – Wasteful waking is better than never waking up

• So why does `notify` exist?
  
  – Well, it is faster when correct…

3/06/2013
Alternate approach

- An alternative is to call `notify` (not `notifyAll`) on every `enqueue / dequeue`, not just when the buffer was empty / full
  - Easy: just remove the `if` statement

- Alas, makes our code subtly wrong since it is technically possible that an `enqueue` and a `dequeue` are both waiting
  - See notes for the step-by-step details of how this can happen

- Works fine if buffer is unbounded since then only dequeuers wait
Alternate approach fixed

- The alternate approach works if the enqueuers and dequeuers wait on different condition variables
  - But for mutual exclusion both condition variables must be associated with the same lock

- Java’s “everything is a lock / condition variable” does not support this: each condition variable is associated with itself

- Instead, Java has classes in `java.util.concurrent.locks` for when you want multiple conditions with one lock
  - `class ReentrantLock` has a method `newCondition` that returns a new `Condition` object associate with the lock
  - See the documentation if curious
Last condition-variable comments

- `notify/notifyAll` often called `signal/broadcast`, also called `pulse/pulseAll`

- Condition variables are subtle and harder to use than locks

- But when you need them, you need them
  - Spinning and other work-arounds do not work well

- Fortunately, like most things in a data-structures course, the common use-cases are provided in libraries written by experts
  - Example: `java.util.concurrent.ArrayBlockingQueue<E>`
  - All uses of condition variables hidden in the library; client just calls `put` and `take`
Concurrency summary

• Access to shared resources introduces new kinds of bugs
  – Data races
  – Critical sections too small
  – Critical sections use wrong locks
  – Deadlocks

• Requires synchronization
  – Locks for mutual exclusion (common, various flavors)
  – Condition variables for signaling others (less common)

• Guidelines for correct use help avoid common pitfalls

• Not clear shared-memory is worth the pain
  – But other models (e.g., message passing) not a panacea
