Hashing Choices HashTable Review 2 1 **1** Choose a hash function Hash Tables Provides $\mathcal{O}(1)$ core Dictionary operations (**on average**) 2 Choose a table size • We call the key space the "universe": U and the Hash Table T• We should use this data structure **only** when we expect |U| >> |T|3 Choose a collision resolution strategy (Or, the key space is non-integer values.) Separate Chaining Linear Probing Quadratic Probing Double Hashing hash function mod |T|· Table Index ^{collision?}→ Fixed Table Index • Other issues to consider: $\rightarrow \text{int}$ Hash Table Client Hash Table Library 4 Choose an implementation of deletion **5** Choose a λ that means the table is "too full" Another Consideration? What do we do when λ (the load factor) gets too large? We discussed the first few of these last time. We'll discuss the rest today.

Review: Collisions

Δ

Definition (Collision)

A collision is when two distinct keys map to the same location in the hash table.

A good hash function attempts to avoid as many collisions as possible, but they are inevitable.

How do we deal with collisions?

There are multiple strategies:

- Separate Chaining
- Open Addressing
 - Linear Probing
 - Quadratic Probing
 - Double Hashing

Open Addressing

Definition (Open Addressing)

Open Addressing is a type of collision resolution strategy that resolves collisions by choosing a different location when the natural choice is full.

There are many types of open addressing. Here's the key ideas:

- We **must** be able to duplicate the path we took.
- We want to use **all** the spaces in the table.
- We want to avoid putting lots of keys close together.

It turns out some of these are difficult to achieve...

Strategy #1: Linear Probing 1 i = 0;

- 2 while (index in use) {
- **try** (h(key) + i) % |T|3 4 }

Example

Insert 38, 19, 8, 109, 10 into a hash table with hash function h(x) = x and linear probing

Open Addressing

Analyzing Linear Probing

Which Criteria Does Linear Probing Meet? We want to use all the spaces in the table. Yes! Linear probing will fill the whole table. We want to avoid putting lots of keys close together. Uh...not so much Primary Clustering Primary Clustering is when different keys collide to form one big group. 8 109 101 20 38 19 T(0) T(1) T(2) T(3) T(4) T(6) T(7) T(8) T(9) •

6

Think of this as "clusters of many colors". Even though these keys are all different, they end up in a giant cluster.

In linear probing, we expect to get $O(\lg n)$ size clusters.

This is really bad! But, how bad, really?

Vindar Quadratic Probing

There's nothing theoretically wrong with open addressing that forces primary clustering. We'd like a different (easy to compute) function to probe with. That is:

Open Addressing In General

Choose a new function f(x) and then probe with

 $(h(\text{key})+i) \mod |T|$

Vinlar Quadratic Probing

There's nothing theoretically wrong with open addressing that forces primary clustering. We'd like a different (easy to compute) function to probe with. That is:

Open Addressing In General

Choose a new function f(x) and then probe with

	Strategy =			Example										
1 2 3 4	<pre>i = 0; while (ind try (h }</pre>			Insert 89,18,49,58,79 into a hash table with hash function $h(x) = x$ and quadratic probing						g				
		T[0]	T[1]	T[2]	T[3]	T[4]	T[5]	T[6]	T[7]	T[8]	89 T[9]]	

Vinear Quadratic Probing

Quadratic Probing: Clustering

With linear probing, we saw primary clustering (keys hashing near each other). Quadratic Probing fixes this by "jumping". Unfortunately, we still get secondary clustering:

11

Secondary Clustering

Secondary Clustering is when different keys hash to the same place and follow the same probing sequence.

Think of this as long probing chains of the same color. The keys all start at the same place; so, the chain gets really long.

We can avoid secondary clustering by using a probe function that depends on the key.

Linear Quadratic Double Hashing

Kinkar Quadratic Double Hashing

Double Hashing Analysis 13 Filling the Table Just like with Quadratic Probing, we sometimes hit an infinite loop with double hashing. We will not get an infinite loop in the case with primes p,q such that 2 < q < p: h(key) = key mod p $\blacksquare g(\text{key}) = q - (\text{key mod } q)$ **Uniform Hashing** For double hashing, we assume **uniform hashing** which means: $\Pr[g(\text{key1}) \mod p = g(\text{key2}) \mod p] = \frac{1}{n}$ Average Number of Probes Successful Search Unsuccessful Search 1 $\frac{1}{\lambda} \ln\left(\frac{1}{1-\lambda}\right)$ $\overline{1-\lambda}$ This is way better than linear probing.

Where We Are

Separate Chaining is Easy!

- find, delete proportional to load factor on average
- insert can be constant if just push on front of list

Open Addressing is Tricky!

- Clustering issues
- Doesn't always use the whole table
- Why Use it?
 - Less memory allocation
 - Easier data representation

Now, let's move on to resizing the table.

Rehashing

When $\boldsymbol{\lambda}$ is too big, create a bigger table and copy over the items

When To Resize

- With separate chaining, we decide when to resize (should be $\lambda \leq 1$)
- With open addressing, we need to keep $\lambda < \frac{1}{2}$

New Table Size?

- Like always, we want around "twice as big"
- ... but it should still be prime
- So, choose the next prime about twice as big

How To Resize

Go through table, do standard insert for each into new table:

- Iterate over old table: $\mathcal{O}(n)$
- *n* inserts / calls to the hash function: $n \times \mathcal{O}(1) = \mathcal{O}(n)$
- But this is amortized $\mathcal{O}(1)$

Hashing and Comparing

A hash function isn't enough! We have to **compare** items:

- With separate chaining, we have to loop through the list checking if the item is what we're looking for
- With open addressing, we need to know when to stop probing

We have two options for this: equality testing or comparison testing.

- In Project 2, you will use two function objects (Hashable and Comparable)
- In Java, each Object has an equals method and a hashCode method
- 1 **class** Object {
- 2 boolean equals(Object o) {...}
- 3 int hashCode() {...}
 4 ...

5 }

Properties of Comparable and Hashable

17

For any class, it **must be the case that**:

- For P2: If c.compare(a, b) == 0, then h.hash(a) == h.hash(b)
- If compare(a, b) < 0, then compare(b, a) > 0
- If compare(a, b) == 0, then compare(b, a) == 0
- If compare(a, b) < 0 and compare(b, c) < 0, then compare(a, c) < 0</pre>

A Good Hashcode

- 1 int result = 17; // start at a prime
- 2 foreach field f
- 3 int fieldHashcode =
- 4 boolean: (f ? 1: 0)
 5 byte, char, short, :
- 5 byte, char, short, int: (int) f
 6 long: (int) (f ^ (f >>> 32))
- 6 long: (int) (f ^ (f >>> 32))
 7 float: Float.floatToIntBits(f)
- 8 double: Double.doubleToLongBits(f), then above
- 9 Object: object.hashCode()
- 10 result = 31 * result + fieldHashcode;
- 11 return result;

Hashing Wrap-Up

- 19
- Hash Tables are one of the most important data structures
 - Efficient find, insert, and delete
 - based on sorted order are not so efficient
 - Useful in many, many real-world applications
 - Popular topic for job interview questions
- Important to use a good hash function
 - Good distribution, uses enough of keys values
 - Not overly expensive to calculate (bit shifts good!)
- Important to keep hash table at a good size
 - Prime Size
 - λ depends on type of table
- What we skipped: Perfect hashing, universal hash functions, hopscotch hashing, cuckoo hashing
