

A First Algorithm for Topological Sort

1. Label ("mark") each vertex with its in-degree
 - Think "write in a field in the vertex"
 - Could also do this via a data structure (e.g., array) on the side
2. While there are vertices not yet output:
 - a) Choose a vertex v with labeled with in-degree of 0
 - b) Output v and *conceptually* remove it from the graph
 - c) For each vertex w adjacent to v (i.e. w such that $(v,w) \in \mathcal{E}$),
 - decrement the in-degree of w

Topological Sort: Running time?

```
labelEachVertexWithItsInDegree();
for(ctr=0; ctr < numVertices; ctr++){
    v = findNewVertexOfDegreeZero();
    put v next in output
    for each w adjacent to v
        w.indegree--;
}
```

Doing better

- The trick is to avoid searching for a zero-degree node every time!
- Keep the "pending" zero-degree nodes in a list, stack, queue, box, table, or something
 - Order we process them affects output but not correctness or efficiency provided add/remove are both $O(1)$

Using a queue:

1. Label each vertex with its in-degree, enqueue 0-degree nodes
2. While queue is not empty
 - a) $v = \text{dequeue}()$
 - b) Output v and remove it from the graph
 - c) For each vertex w adjacent to v (i.e. w such that $(v,w) \in \mathcal{E}$), decrement the in-degree of w , if new degree is 0, enqueue it

Topological Sort(optimized): Running time?

```
labelAllAndEnqueueZeros();
for(ctr=0; ctr < numVertices; ctr++){
    v = dequeue();
    put v next in output
    for each w adjacent to v {
        w.indegree--;
        if(w.indegree==0)
            enqueue(w);
    }
}
```

DFS with a stack, Example: trees

```

DFS2(Node start) {
  initialize stack s to hold start
  mark start as visited
  while(s is not empty) {
    next = s.pop() // and "process"
    for each node u adjacent to next
      if(u is not marked)
        mark u and push onto s
  }
}
    
```

Order processed:

- A different but perfectly fine traversal

30

BFS with a queue, Example: trees

```

BFS(Node start) {
  initialize queue q to hold start
  mark start as visited
  while(q is not empty) {
    next = q.dequeue() // and "process"
    for each node u adjacent to next
      if(u is not marked)
        mark u and enqueue onto q
  }
}
    
```

Order processed:

- A "level-order" traversal

Saving the path

- Our graph traversals can answer the "reachability question":
 - "**Is there** a path from node x to node y?"
- Q: But what if we want to **output the actual path**?
 - Like getting driving directions rather than just knowing it's possible to get there!
- A: Like this:
 - Instead of just "marking" a node, store the **previous node** along the path (when processing u causes us to add v to the search, set v.path field to be u)
 - When you reach the goal, follow path fields backwards to where you started (and then reverse the answer)
 - If just wanted path length, could put the integer distance at each node instead

35

Example using BFS

What is a path from Seattle to Austin

- Remember marked nodes are not re-enqueued
- Note shortest paths may not be unique
