- ❖ Find the shortest path from A to E ...
  - ... assuming this graph is unweighted
  - ... assuming this graph is weighted
  - (don't worry about finding a general algorithm; just find the path manually)

# Lecture Outline

- ❖ **Topological Sort (cont.)**
  
- ❖ Traversals
  - Introduction
  - Trees and Graphs: Level-order / Breadth-first
  - Trees: Three Flavors of Depth-first
  - Graphs: Depth-first
  - Conclusion
  
- ❖ Shortest Paths!
  
- ❖ Dijkstra's Algorithm

Disclaimer: Do not use for official advising purposes!  
Falsely implies CSE 332 is a prereq for CSE 312, etc.

# Topological Sort

- ❖ Output all the vertices of a DAG in an order such that no vertex appears before any other vertex that has a path to it
  - A DAG represents a *partial order*, and a topological sort produces a *total order* that is consistent with it

- ❖ Example input:

- ❖ Example output:

- 126, 142, 143, 311, 331, 332, 312, 341, 351, 333, 352, 440

# TopoSort: A Naïve Algorithm

1. Label (“mark”) each vertex with its in-degree
  - Could write directly into a vertex’s field or a parallel data structure (e.g., array)
2. While there are vertices not yet output:
  - Choose a vertex  $v$  with labeled with in-degree of 0
  - Output  $v$  and conceptually remove it from the graph
  - Foreach vertex  $w$  adjacent to  $v$ :
    - Decrement the in-degree of  $w$

# TopoSort: Notes

- ❖ Needed a vertex with in-degree of 0 to start
  - Remember: graph must be acyclic!
- ❖ If  $>1$  vertex with in-degree=0, can break ties arbitrarily
  - Potentially many different correct orders!

# Naïve TopoSort: Running Time?

```

    ① labelEachVertexWithItsInDegree ();
    for (i=0; i < numVertices; i++){
    ②   v = findNewVertexOfDegreeZero ();
    ③   put v in output
    ④   [foreach w adjacent to v
        w.indegree--;
    ]
    }
  
```

do this block  $|V|$  times

- ①  $|V| + |E|$
  - ②  $|V|^2 \leftarrow |V| \text{ work, } |V| \text{ times}$
  - ③  $|V| \leftarrow \Theta(1) \text{ work, } |V| \text{ times}$
  - ④  $|E| \leftarrow O(|V|^2)$ , but  $\Theta(E)$  is tighter (since once per edge)
- $O(|V|^2 + |E|)$

|   | In-Degree | Adj List |
|---|-----------|----------|
| 0 |           | → 3      |
| 1 |           | → 2 → 3  |
| 2 |           | → 4      |
| 3 |           | → 4      |
| 4 |           | /        |

# TopoSort's Runtime: Doing Better

- ❖ Avoid searching for a zero-degree node every time!
  - Keep the “pending” 0-degree nodes in a list, stack, queue, table, etc
  - The order we process them affects output, but not correctness or efficiency (*as long as add/remove are both  $O(1)$* )
  
- ❖ Using a queue:
  - Label each vertex with its in-degree, enqueueing 0-degree nodes
  - While “pending” queue is not empty:
    - $v = \text{dequeue}()$
    - Output  $v$  and remove it from the graph
    - For each vertex  $w$  adjacent to  $v$  (i.e.  $w$  such that  $(v,w)$  in  $E$ ):
      - decrement the in-degree of  $w$
      - if new degree is 0, enqueue it

# Better TopoSort: Running Time?

```

    ① pending = labelAllAndReturnZeros ();
    while ( !pending.empty() ) {
    ②   v = pending.dequeue ();
    ③   put v in output
    ④   [ foreach w adjacent to v
          w.indegree--;
          if (w.indegree == 0)
            pending.enqueue (w);
        ]
    }
  
```

- ①  $|V| + |E|$
- ②  $|V| \leftarrow \Theta(1)$  work,  $|V|$  time
- ③  $|V| \leftarrow$  same as above
- ④  $|E| \leftarrow$  same as before

$$O(|V| + |E|)$$

|   | In-Degree | Adj List |
|---|-----------|----------|
| 0 |           | → 3      |
| 1 |           | → 2 → 3  |
| 2 |           | → 4      |
| 3 |           | → 4      |
| 4 |           | /        |

# Lecture Outline

- ❖ Topological Sort (cont.)
  
- ❖ Traversals
  - **Introduction**
  - Trees and Graphs: Level-order / Breadth-first
  - Trees: Three Flavors of Depth-first
  - Graphs: Depth-first
  - Conclusion
  
- ❖ Shortest Paths!
  
- ❖ Dijkstra's Algorithm

# Tree and Graph Reachability

- ❖ Find all vertices *reachable* from a starting vertex  $v$ 
  - ie, there exists a path
  - Might “do something” at each visited vertex (an iterator!)
    - “Do something” is called *visiting* or *processing* a vertex
      - eg, print to output, set some field, etc.
    - *Traversing* a vertex or *iterating* over a vertex is different!
      - Just fetch adjacent/child vertices
  
- ❖ Related Questions:
  - Is an undirected graph connected?
  - Is a directed graph weakly / strongly connected?
    - For strongly, need a cycle back to starting vertex *for each vertex in the graph*

# Tree and Graph Traversals

- ❖ Can answer reachability with a tree or graph *traversal*
  - Iterates over every vertex in a graph in some defined ordering
  - “Processes” or “visits” its contents
  
- ❖ There are several types of tree traversals
  - Level Order Traversal aka Breadth-First Traversal
  - Depth-First Traversal
    - Pre-order Traversal
    - In-order Traversal
    - Post-order Traversal

# Tree/Graph Traversals Follow a Pattern

## 1. Initialization:

- Create an empty data structure to track “remaining work”
- Mark start as visited

## 2. While we still have work, follow the vertices:

### 3. Get a vertex

### 4. Visit/process that vertex

### 5. Update its neighbors (eg, add to “remaining work” if it's not already there)

order depends on algo

```
traverseGraph(Vertex start) {  
    pending = {start}  
    mark start as visited  
  
    while (!pending.empty()) {  
        next = pending.remove()  
        process(next)  
        foreach u adjacent to next  
            if (!u.marked)  
                mark u  
                pending.add(u)  
    }  
}
```

# Tree/Graph Traversal: Running Time

- ❖ Assuming  $\text{add}()$  and  $\text{remove}()$  are  $O(1)$ , traversal is  $O(|E|)$ 
  - Remember: we default to using an adjacency list

# Tree/Graph Traversal: Order

- ❖ The order we process() depends *entirely* on how pending.add() and pending.remove() are implemented
  - Queue:
    - Tree: Level-order
    - Graph: Breadth-first search (BFS)
  - Stack:
    - Tree: Depth-first (3 flavors!)
    - Graph: Depth-first search (DFS)
  - ... and more?
  
- ❖ DFS and BFS are “big ideas” in computer science
  - Depth: explore one part before exploring other unexplored parts
  - Breadth: explore parts closer to the start before exploring farther parts

# Lecture Outline

- ❖ Topological Sort (cont.)
  
- ❖ Traversals
  - Introduction
  - **Trees and Graphs: Level-order / Breadth-first**
  - Trees: Three Flavors of Depth-first
  - Graphs: Depth-first
  - Conclusion
  
- ❖ Shortest Paths!
  
- ❖ Dijkstra's Algorithm

# Trees: Level-Order / BFS

- ❖ Process top-to-bottom, left-to-right
  - Goes “broad” instead of “deep”
  - Requires a queue to track need-to-explore vertices, which is sometimes called the *fringe*
- ❖ Resembles how we converted our binary heap (ie, a complete tree) to its array representation

```
levelOrderTraverse (Vertex root) {  
    q.enqueue (root)  
    while (!q.empty ())  
        next = q.dequeue ()  
        process (next)  
        foreach u in next.children  
            q.enqueue (u)  
}
```

1. Initialize aux data structure
2. Have vertices in data struct?
3. Get vertex from data struct
4. Visit/process vertex
5. Update vertex's neighbors

# Graphs: Breadth-First

- ❖ When working with graphs, we refer to level-order traversals as breadth-first traversals
  - We also need to verify if a vertex has been visited – why?

```
breadthFirstTraversal (Vertex start) {  
    q.enqueue (start)  
    mark start as visited  
  
    while (!q.empty ())  
        next = q.dequeue ()  
        process (next)  
        foreach u in next.neighbors  
            if (!u.marked)  
                mark u  
                q.enqueue (u)  
}
```

1. Initialize aux data structure
2. Have vertices in data struct?
3. Get vertex from data struct
4. Visit/process vertex
5. Update vertex's neighbors

# Lecture Outline

- ❖ Topological Sort (cont.)
  
- ❖ Traversals
  - Introduction
  - Trees and Graphs: Level-order / Breadth-first
  - **Trees: Three Flavors of Depth-first**
  - Graphs: Depth-first
  - Conclusion
  
- ❖ Shortest Paths!
  
- ❖ Dijkstra's Algorithm

# Trees: Depth-First Traversal

- ❖ Process deep vertices before shallow ones

- Eg, visit A before F
- Succinct implementation if using recursion; otherwise, requires a stack to track need-to-explore vertices

```
traverseIter(Node start) {  
  s.push(start)  
  while (!s.empty())  
    next = s.pop()  
    process(next)  
    foreach u in next.neighbors  
      q.push(u)  
}
```

1. Initialize aux data structure
2. Have vertices in data struct?
3. Get vertex from data struct
4. Visit/process vertex
5. Update vertex's neighbors

```
traverseRecur(Node x) {  
  if (x == null)  
    return;  
  process(x.key)  
  foreach c in x.children  
    traverseRecur(c)  
}
```

# Trees: Depth-First: Pre-Order

- ❖ Pre-order “visits” the node before traversing its children
  - DBACFEG

```
preOrder(Node x) {  
    if (x == null)  
        return;  
    process(x.key)  
    preOrder(x.left)  
    preOrder(x.right)  
}
```

# Trees: Depth-First: In-Order

- ❖ Pre-order “visits” the node before traversing its children
  - DBACFEG
- ❖ In-order traverses the left child, “visits” the node, then traverses the right child
  - ABCDEF

```
preOrder(Node x) {  
    if (x == null)  
        return;  
    process(x.key)  
    preOrder(x.left)  
    preOrder(x.right)  
}
```

```
inOrder(Node x) {  
    if (x == null)  
        return;  
    inOrder(x.left)  
    process(x.key)  
    inOrder(x.right)  
}
```

# Trees: Depth-First: Post-Order

- ❖ Pre-order “visits” the node before traversing its children

- DBACFEG

- ❖ In-order traverses the left child, “visits” the node, then traverses the right child

- ABCDEF

- ❖ Post-order traverses its children before “visiting” the node

- ACBEGFD

```

preOrder(Node x) {
    if (x == null)
        return;
    process(x.key)
    preOrder(x.left)
    preOrder(x.right)
}
  
```

```

inOrder(Node x) {
    if (x == null)
        return;
    inOrder(x.left)
    process(x.key)
    inOrder(x.right)
}
  
```

```

postOrder(Node x) {
    if (x == null)
        return;
    postOrder(x.left)
    postOrder(x.right)
    process(x.key)
}
  
```

note the root's position!

# Useful Trick for Depth-First Tree Traversals

- ❖ *(Useful for humans, not algorithms)*
- ❖ Trace a path around the graph, from the top going counter-clockwise
  - *Pre-order*: Process when you pass LEFT side of a node
  - *In-order*: Process when you pass BOTTOM of a node
  - *Post-order*: Process when you pass the RIGHT side of a node.

*Post-order*: 4 7 8 5 2 9 6 3 1

  - Trees: Three Flavors of Depth-first
  - **Graphs: Depth-first**
  - Conclusion
  
- ❖ Shortest Paths!
  
- ❖ Dijkstra's Algorithm

# Trees and Graphs: Depth-First

- ❖ Still processing “far vertices” before “near” ones
  - Still has recursive and iterative implementations
  - Still must mark previously-visited nodes

```
depthFirstTraversal(Vertex start) {  
    s.push(start)  
    mark start as visited  
  
    while (!s.empty())  
        next = s.pop()  
        process(next)  
        foreach u in next.neighbors  
            if (!u.marked)  
                mark u  
                s.push(u)  
}
```

1. Initialize aux data structure
2. Have vertices in data struct?
3. Get vertex from data struct
4. Visit/process vertex
5. Update vertex's neighbors

  - Introduction
  - Trees and Graphs: Level-order / Breadth-first
  - Trees: Three Flavors of Depth-first
  - Graphs: Depth-first
  - **Conclusion**
  
- ❖ Shortest Paths!
  
- ❖ Dijkstra's Algorithm

# Saving the Path

- ❖ These graph traversals can answer the “reachability question”:
  - “Is there a path from vertex  $x$  to vertex  $y$ ?”
  
- ❖ But what if we want to output the actual path or its length?
  - Eg, getting driving directions vs knowing it's possible to get there
  
- ❖ Modifications:
  - Instead of just “marking” a vertex, store the path's previous vertex
    - ie: when processing  $u$ , set  $v.\text{prev}$  to  $u$
  - When you reach the goal, follow  $\text{prev}$  fields backwards to start
    - (don't forget to reverse the answer)
  - Path length:
    - Same idea, but also store integer distance at each vertex

# Saving the Path: Example using BFS (1 of 2)

- ❖ Find the shortest path from Seattle to Austin
  - Remember marked vertices are not re-enqueued
  - Shortest paths may not be unique

## Saving the Path: Example using BFS (2 of 2)

- ❖ Find the shortest path from Seattle to Austin
  - Remember marked vertices are not re-enqueued
  - Shortest paths may not be unique

# DFS/BFS Comparison

- ❖ Breadth-first search:
  - Always finds shortest paths, i.e., finds “optimal solutions”
    - Better for “what is the shortest path from x to y?”
  - But queue may hold up to  $O(|V|)$  vertices
    - Eg, at the bottom level of perfect binary tree, queue contains  $|V|/2$  vertices
  
- ❖ Depth-first search:
  - Can use less space when finding a path
    - If longest path in the graph is  $p$  and highest out-degree is  $d$  then stack never has more than  $d \cdot p$  elements

# It Doesn't Have to be Either/Or

- ❖ A third approach: Iterative deepening (IDDFS):
  - Try DFS, but don't allow recursion more than  $K$  levels deep
  - If fails to find a solution, increment  $K$  and start the entire search over
- ❖ Like BFS, finds shortest paths. Like DFS, less space

# Lecture Outline

- ❖ Topological Sort
  
- ❖ Traversals
  - Introduction
  - Trees and Graphs: Level-order / Breadth-first
  - Trees: Three Flavors of Depth-first
  - Graphs: Depth-first
  - Conclusion
  
- ❖ **Shortest Paths!**
  
- ❖ Dijkstra's Algorithm

# Single-Source Shortest Paths

- ❖ We've seen BFS finds the minimum path length from  $v$  to  $u$ 
  - Runtime:  $O(|E| + |V|)$
- ❖ Actually, BFS finds the min path length from  $v$  to *every vertex*
  - Still  $O(|E| + |V|)$
  - Worst-case runtime for single-destination is no faster than worst-case runtime for all-destinations

# Shortest Path: Applications

- ❖ Network routing
- ❖ Driving directions
- ❖ Cheap flight tickets
- ❖ Critical paths in project management (see textbook)
- ❖ ...

*Wait, these are all weighted graphs!*

## Single-Source Shortest Paths ... *for Weighted Graphs*

Given a weighted graph and vertex  $v$ ,  
find the minimum-cost path from  $v$  to every vertex

- ❖ As before:
  - All-destinations is asymptotically no harder than single-destination
- ❖ Unlike before:
  - BFS will not work

# BFS for Weighted Graphs

- ❖ BFS doesn't work! Shortest path may not have fewest edges
  - Eg: cost of flight. May be cheaper to fly through a hub than fly direct

- ❖ We will assume there are *no negative edge weights*
  - Entire problem is *ill-defined* if there are negative-cost cycles
  - Today's algorithm is *wrong* if there are negative-cost edges

# Negative Cycles vs Negative Edges

- ❖ *Negative cycles*: no algorithm can find a finite optimal path
  - You can always decrease the distance by going through the negative cycle a few more times
  
- ❖ *Negative edges*: Dijkstra's can't guarantee correctness
  - But other algorithms might

# Lecture Outline

  - Trees: Three Flavors of Depth-first
  - Graphs: Depth-first
  - Conclusion
  
- ❖ Shortest Paths!
  
- ❖ **Dijkstra's Algorithm**

# Dijkstra's Algorithm

- ❖ Named after its inventor, Edsger Dijkstra (1930-2002)
  - Truly one of the “founders” of computer science
  - 1972 Turing Award
  - This algorithm is just *one* of his many contributions!
  - Example quote: “Computer science is no more about computers than astronomy is about telescopes”
- ❖ The idea: reminiscent of BFS, but adapted to handle weights
  - Grow the set of vertices whose shortest distance has been computed
  - Vertices not in the set will have a “best distance so far”

# Dijkstra's Algorithm: Idea

## ❖ Initialization:

- Start vertex has distance **0**; all other vertices have distance  $\infty$

## ❖ At each step:

- Pick closest unknown vertex  $v$
- Add it to the "cloud" of known vertices
- Update distances for vertices with edges from  $v$

1. Initialize aux data structure
2. Have vertices in data struct?
3. Get vertex from data struct
4. Visit/process vertex
5. Update vertex's neighbors

# Dijkstra's Algorithm: Pseudocode

```
dijkstra(Graph g, Vertex start) {
  foreach vertex v in g:
    v.distance =  $\infty$ 
    v.known = false
  start.distance = 0

  while there are vertices in g that are not known:
    select vertex v with lowest cost
    v.known = true
    foreach unknown v.neighbor with weight w:
      d1 = v.distance + w // best path through v to u
      d2 = u.distance // previous best path to u
      if (d1 < d2): // if this is a better path to u
        u.distance = d1
        u.previous = v // backtracking info to
                        // recreate path
}
```

# Dijkstra's Algorithm: Important Features

- ❖ Once a vertex is marked known, its shortest path is known
  - Can reconstruct path by following back-pointers (“previous” fields)
- ❖ While a vertex is not known, another shorter path might be found

# Dijkstra's Algorithm vs BFS

```
dijkstra(Graph g, Vertex start) {  
  
    foreach vertex v in g:  
        v.distance =  $\infty$   
        v.known = false  
    start.distance = 0  
  
    while there are unknown vertices:  
        v = lowest cost unknown vertex  
        v.known = true  
        foreach unknown v.neighbor  
        with weight w:  
            d1 = v.distance + w  
            d2 = u.distance  
            if (d1 < d2):  
                u.distance = d1  
                u.previous = v  
  
}
```

```
breadthFirst(Graph g,  
              Vertex start) {  
    q.enqueue(start)  
  
    mark start as visited  
  
    while (!q.empty())  
        next = q.dequeue()  
        process(next)  
        foreach u in next.neighbors  
  
            if (!u.marked)  
                mark u  
  
        q.enqueue(u)  
  
}
```

# Dijkstra's Algorithm: Example #1

Best distance from A, so far
