

CSE 333

Lecture 16 - starting in on subclasses

Steve Gribble

Department of Computer Science & Engineering

University of Washington

Administrivia

HW3 is out today

- due in two weeks
- you can work solo, or in teams of two

Your midterm is...

- on Monday May 9th
 - it covers C, C++ up to, and including, lec14
 - **DO ALL OF THE EXERCISES FROM LEC1 - LEC14!**

Section tomorrow

- details on C++ subclasses, inheritance

Today

Go through HW3

- lots of details to understand and master

Start in on C++ inheritance

- *huge thanks to Marty Stepp for his “portfolio” case study*

Let's build a stock portfolio

A portfolio represents a person's financial investments

- each asset has a cost (how much was paid for it) and a market value (how much it is worth)
 - ▶ the difference is the profit (or loss)
- different assets compute market value in different ways
 - ▶ **stock**: has a symbol ("GOOG"), a number of shares, share price paid, and current share price
 - ▶ **dividend stock**: is a stock that also has dividend payments
 - ▶ **cash**: money; never incurs profit or loss. (hah!)

One possible design

Stock
symbol_ total_shares_ total_cost_ current_price_
GetMarketValue() GetProfit() GetCost()

DividendStock
symbol_ total_shares_ total_cost_ current_price_ dividends_
GetMarketValue() GetProfit() GetCost()

Cash
amount_
GetMarketValue()

One class per asset type

- Problem: redundancy
- Problem: cannot treat multiple investments the same way
 - ▶ e.g., cannot put them in a single array or Vector

see initial_design/

Inheritance

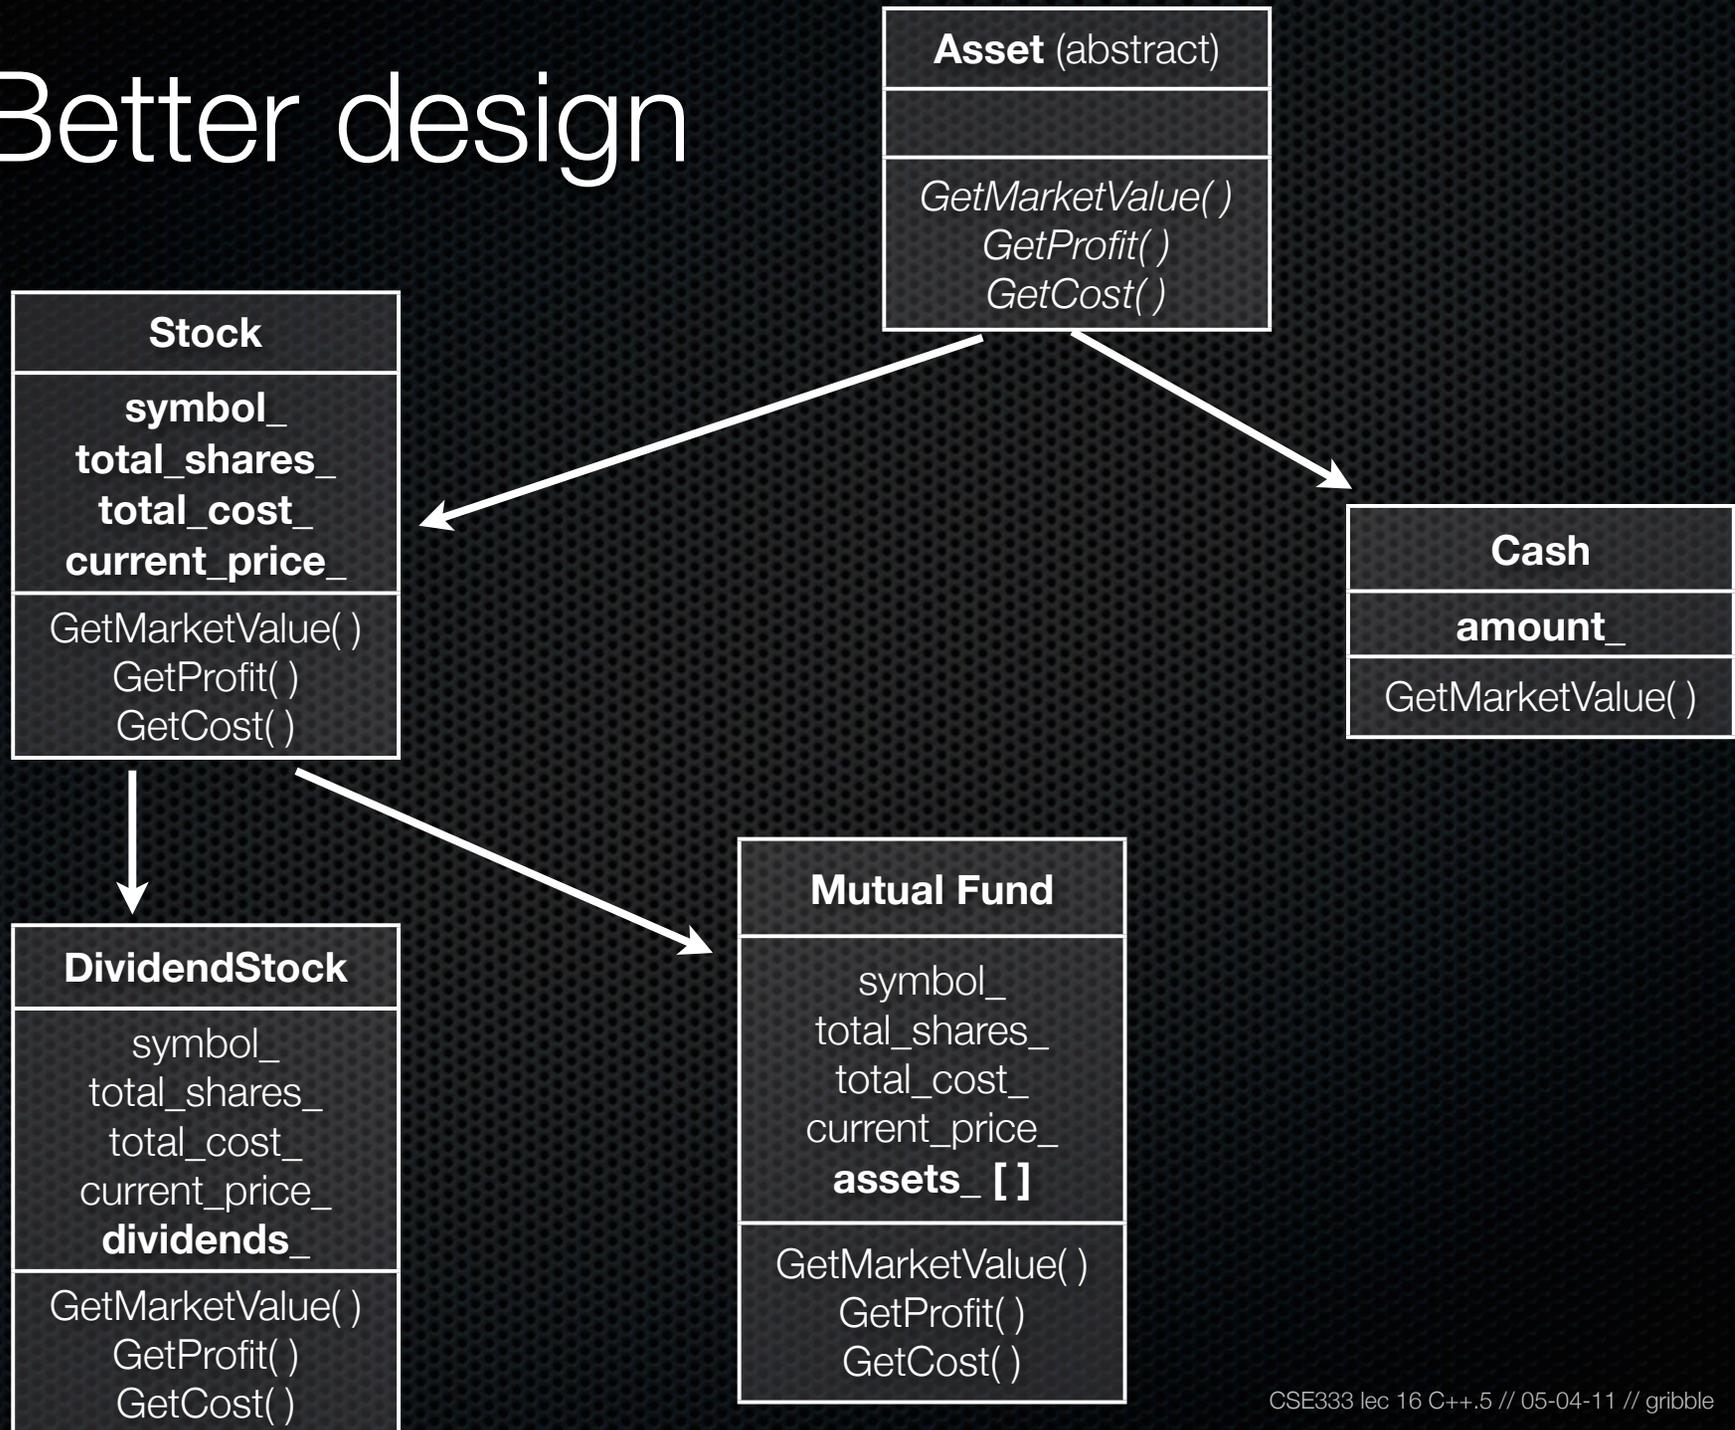

A parent-child relationship between classes

- a child (**derived** class) extends a parent (**base** class)

Benefits:

- code reuse: subclasses inherit code from superclasses
- polymorphism
 - ▶ ability to redefine existing behavior but preserve the interface
 - ▶ children can override behavior of parent
 - ▶ others can make calls on objects without knowing which part of the inheritance tree it is in
- extensibility: children can add behavior

Better design

Access specifiers

public: visible to all other classes

protected: visible to current class and its subclasses

private: visible only to the current class

declare a member as **protected** if:

- you don't want random customers accessing them
 - you want to be subclassed and to let subclasses access them

Public inheritance

```
#include "BaseClass.h"

class Name : public BaseClass {
    ...
};
```

- “public” inheritance
 - ▶ anything that is [*public, protected*] in the base is [*public, protected*] in the derived class
- derived class inherits **almost** all behavior from the base class
 - ▶ not constructors and destructors
 - ▶ not the assignment operator or copy constructor

fix DividendStock in next_design/

See you on Friday!
