

# CSE 333

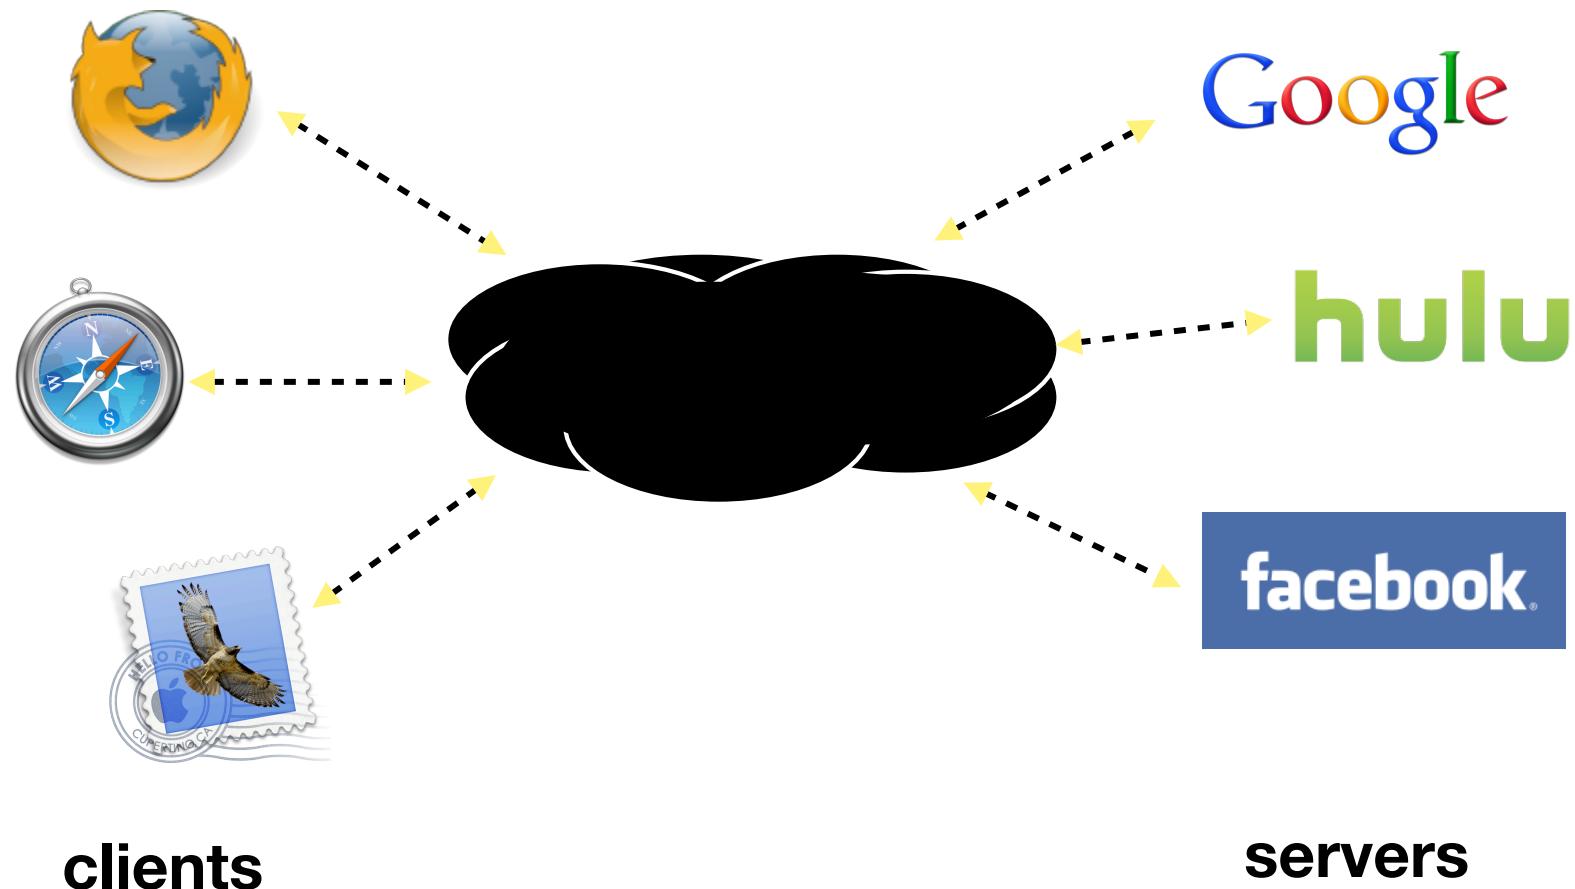

## Lecture 16 -- networks

**Steve Gribble**

Department of Computer Science & Engineering  
University of Washington

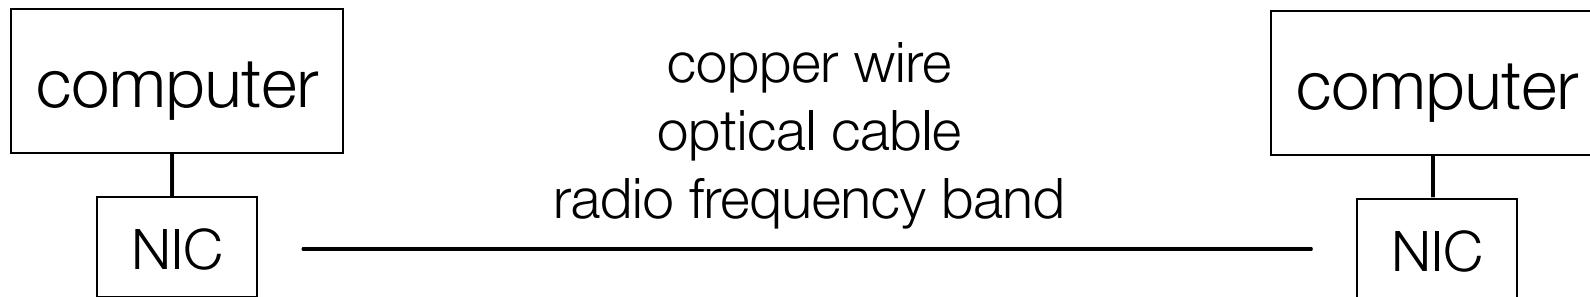

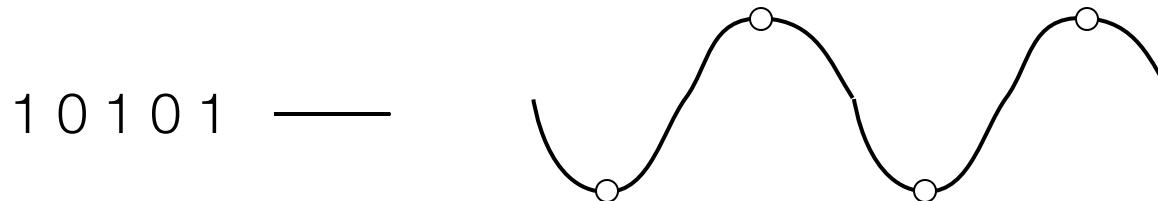

# Networks from 10,000ft

# The “physical” layer

Individual bits are modulated onto a wire or transmitted over radio

- physical layer specifies how bits are encoded at a signal level
- e.g., a simple spec would encode “1” as +1V, “0” as -1V

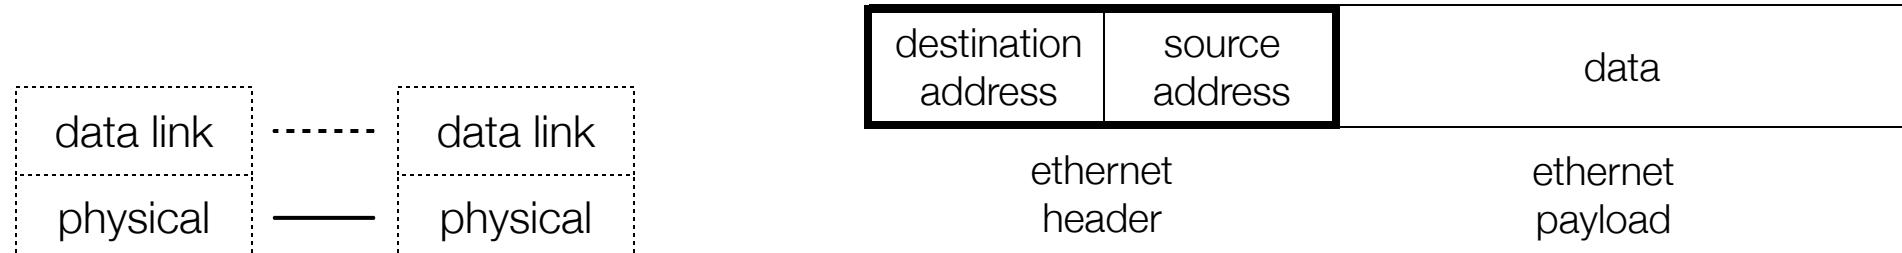

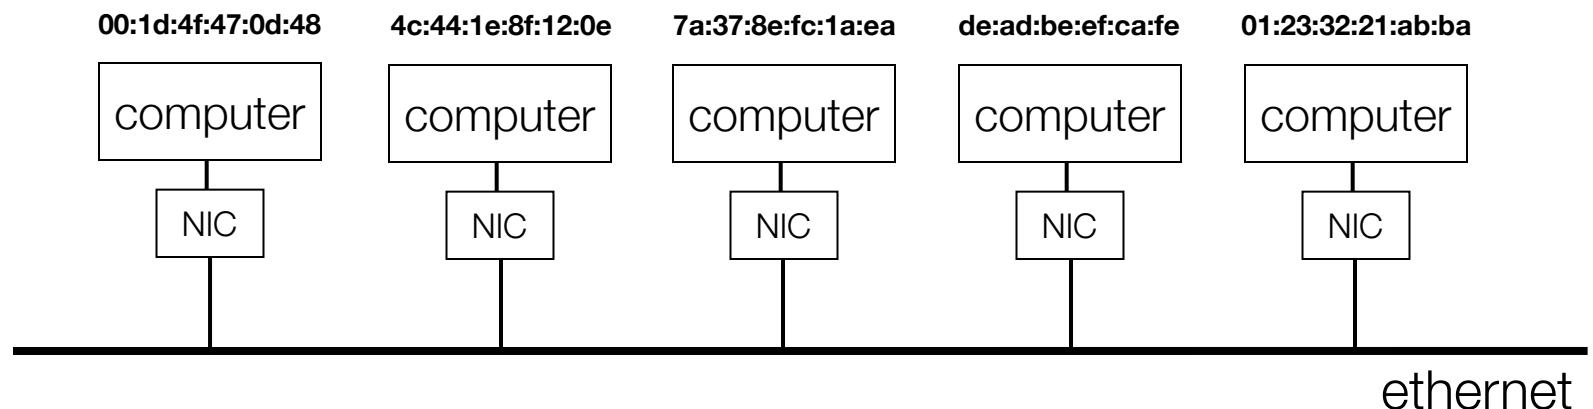

physical

physical

# The “data link” layer

Multiple computers on a LAN contend for the network medium

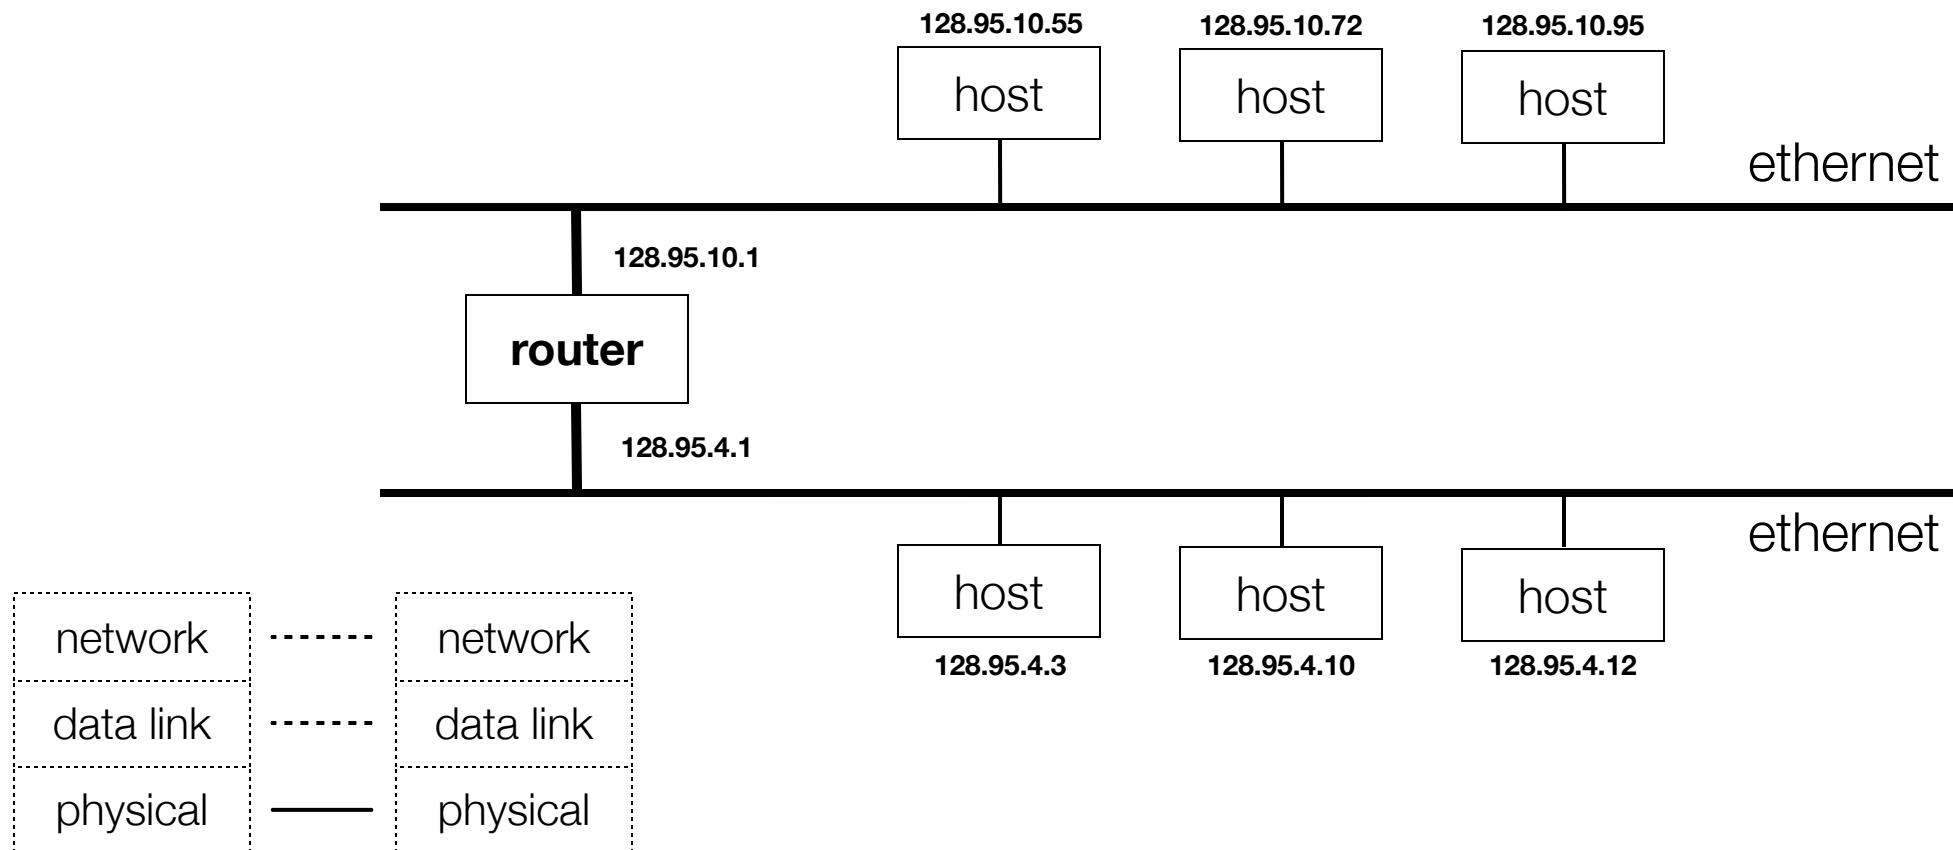

- media access control (MAC) specifies how computers cooperate
- link layer also specifies how bits are packetized and NICs are addressed

# The “network” layer (IP)

The Internet Protocol (IP) routes packets across multiple networks

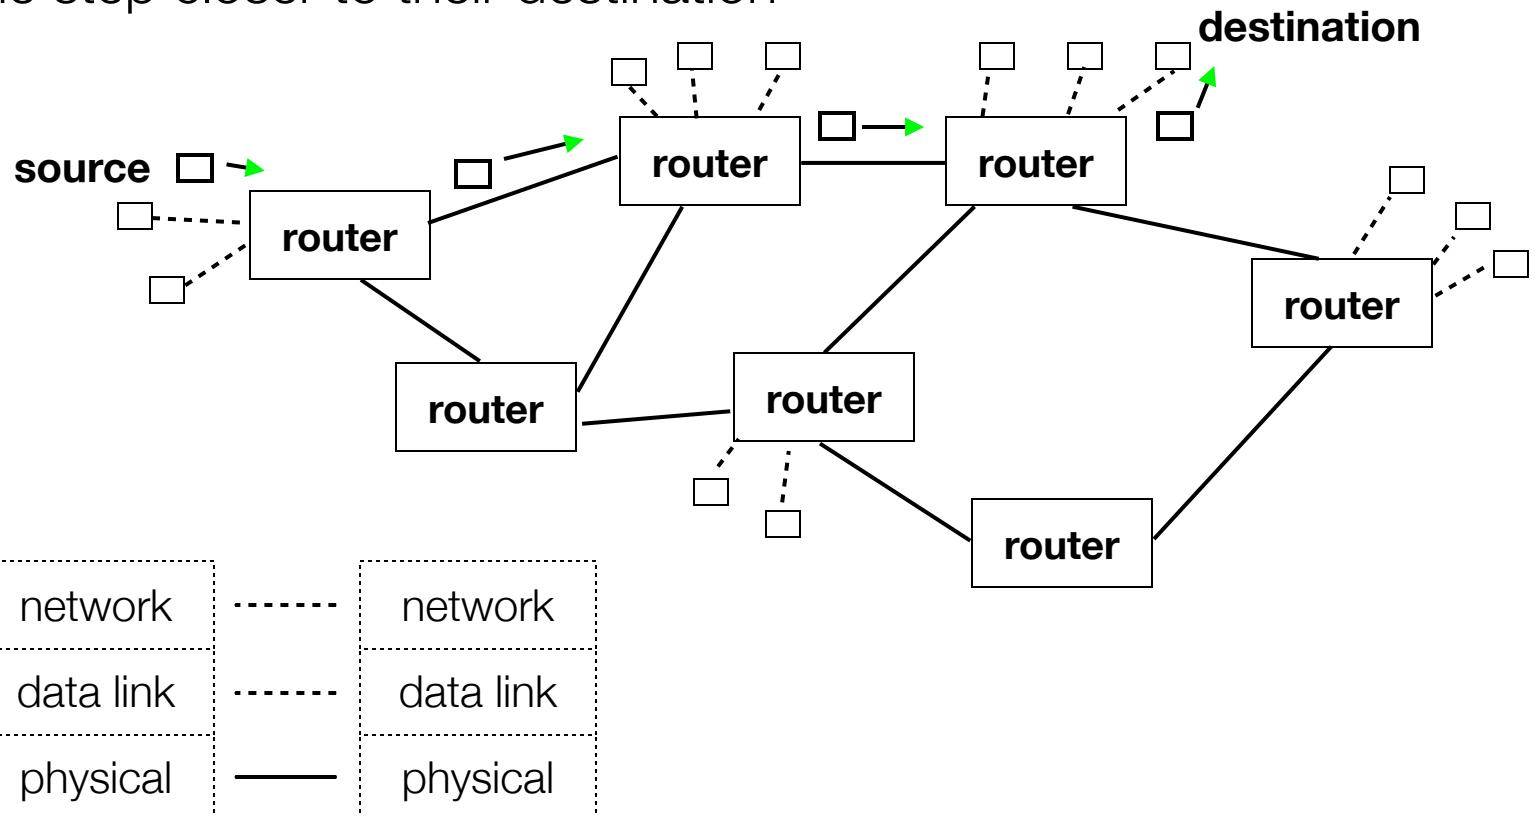

- every computer has a unique Internet address (IP address)
- individual networks are connected by routers that span networks

# The “network” layer (IP)

Protocols to:

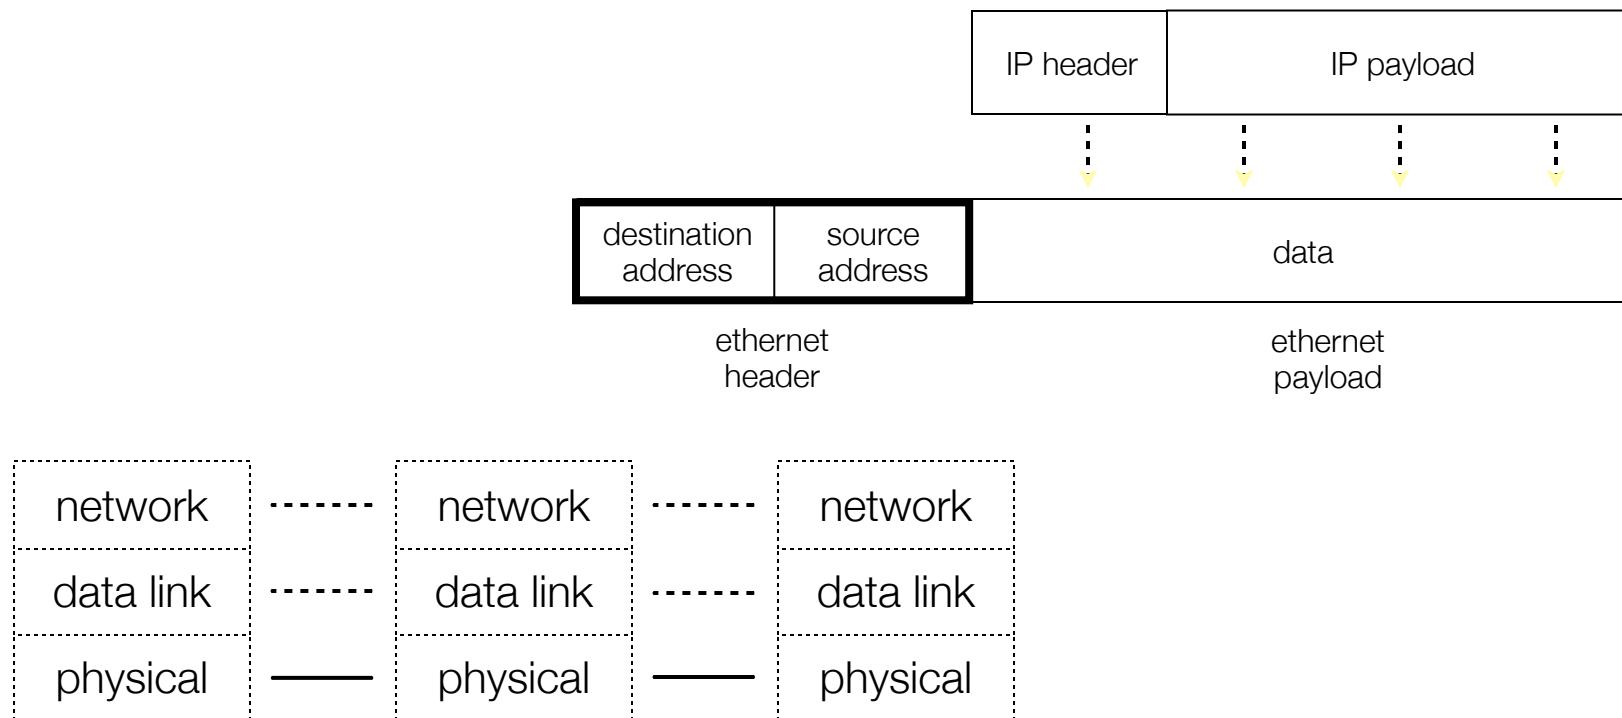

- let a host find the MAC address of an IP address on the same network
- let a router learn about other routers and figure out how to get IP packets one step closer to their destination

# The “network” layer (IP)

## Packet encapsulation

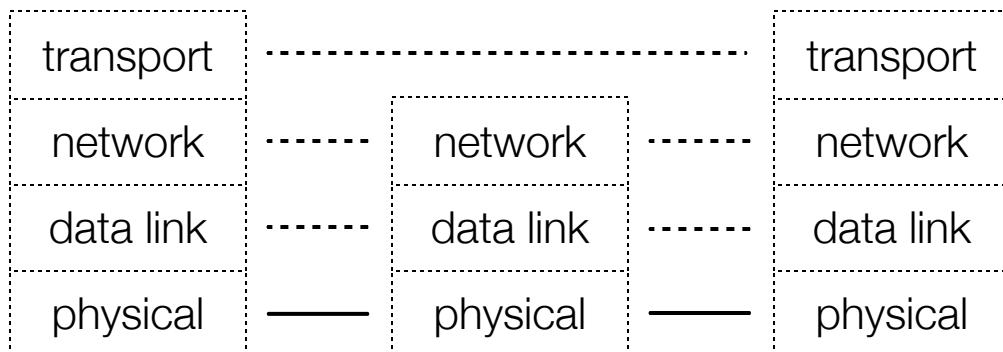

- an IP packet is encapsulated as the payload of an Ethernet frame
- as IP packets traverse networks, routers pull out the IP packet from an ethernet frame and plunk it into a new one on the next network

# The “transport” layer (TCP, UDP)

## TCP

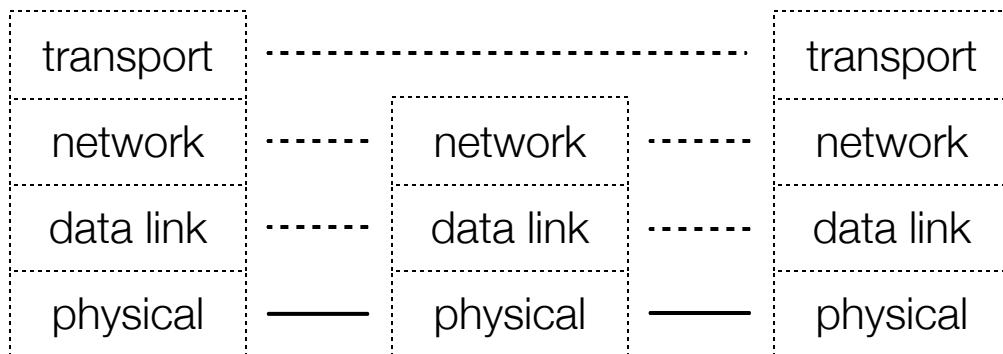

- the “transmission control protocol”
- provides apps with reliable, ordered, congestion-controlled byte streams
- fabricates them by sending multiple IP packets, using sequence numbers to detect missing packets, and retransmitting them
- a single host (IP address) can have up to 65,535 “ports”
  - kind of like an apartment number at a postal address

# The “transport” layer (TCP, UDP)

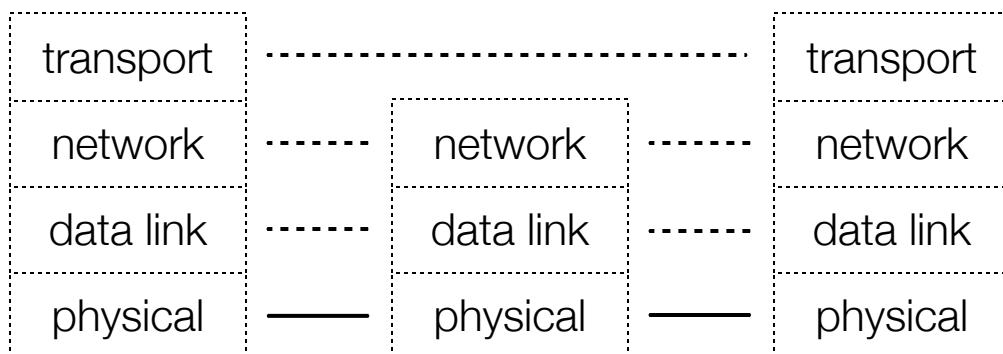

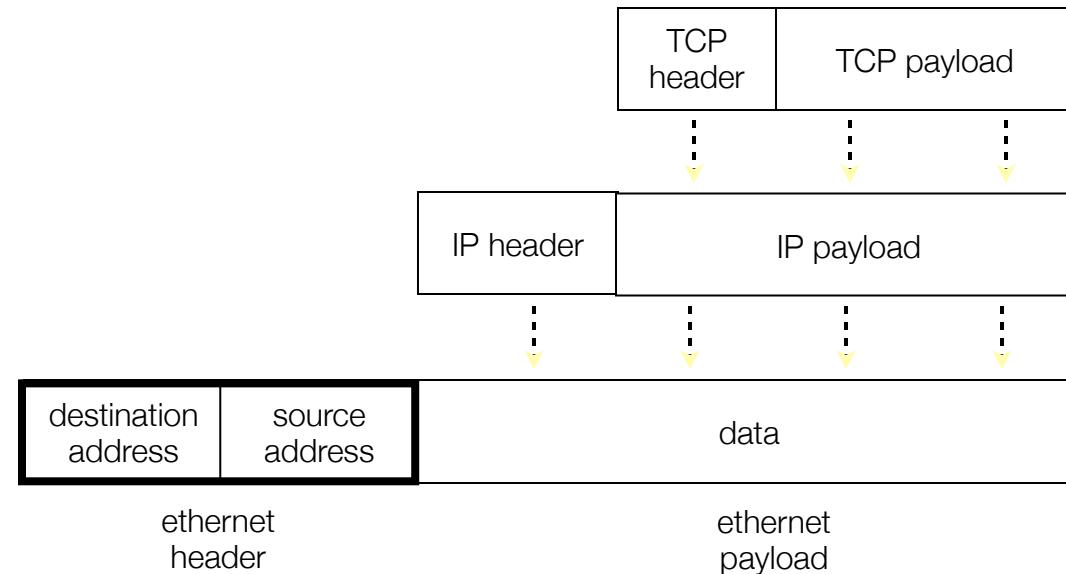

## TCP

- ▶ useful analogy: how would you send a book by mail via postcards?
- ▶ split the book into multiple postcards, send each one by one, including sequence numbers that indicate the assembly order
- ▶ receiver sends back postcards to acknowledge receipt and indicate which got lost in the mail

# The “transport” layer (TCP)

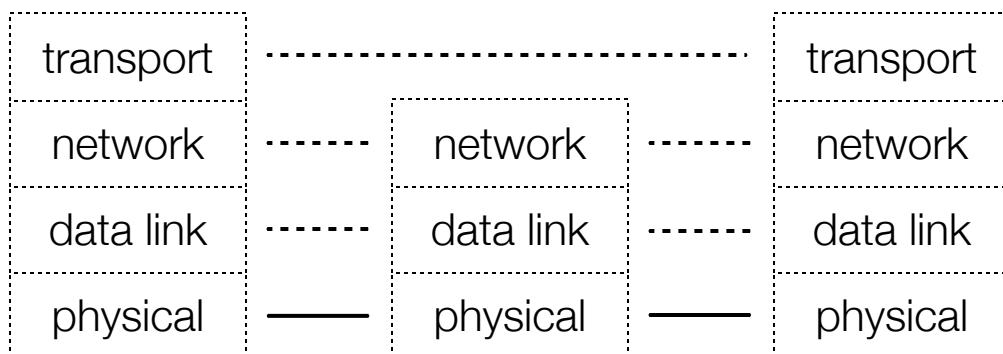

Packet encapsulation -- same as before!

# The “transport” layer (TCP)

Applications use OS services to establish TCP streams

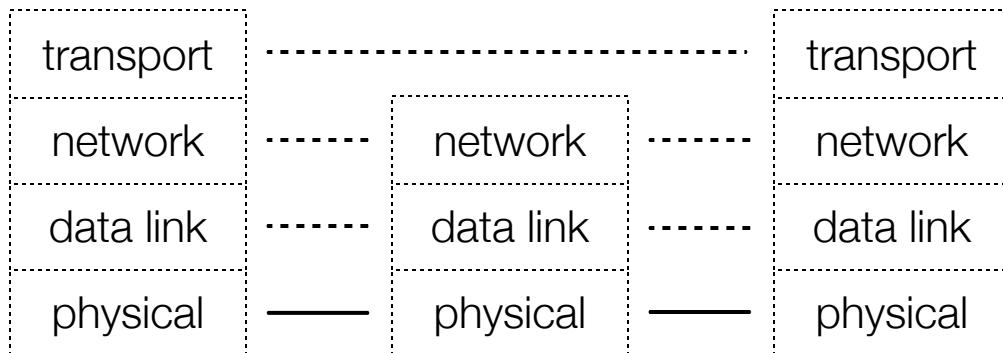

- the “Berkeley sockets” API -- a set of OS system calls
- clients **connect()** to a server IP address + application port number
- servers **listen()** for and **accept()** client connections
- clients, servers **read()** and **write()** data to each other

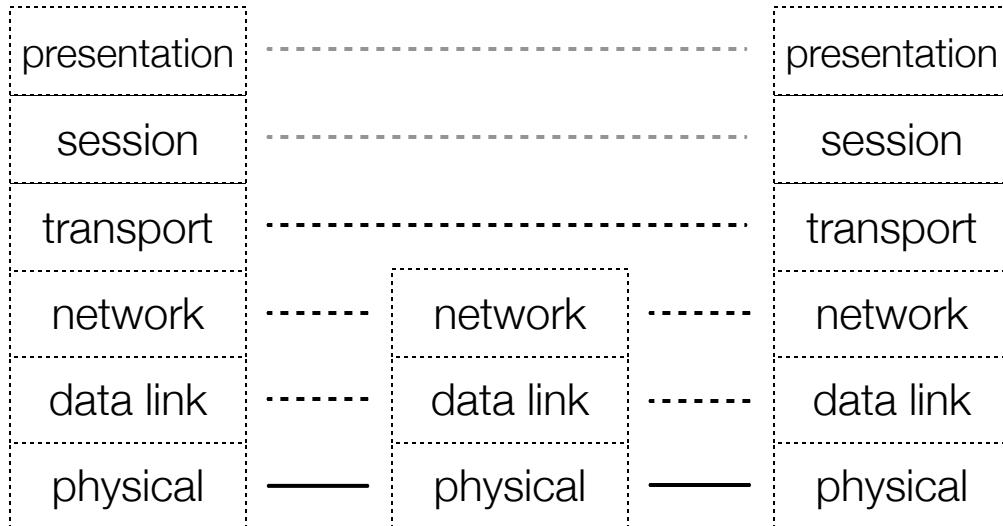

# The “transport” layer (UDP)

## UDP

- ▶ the “user datagram protocol”
- ▶ provides apps with unreliable packet delivery
- ▶ UDP datagrams are fragmented into multiple IP packets
  - ▶ UDP is a really thin, simple layer on top of IP

# The (mostly missing) layers 5,6

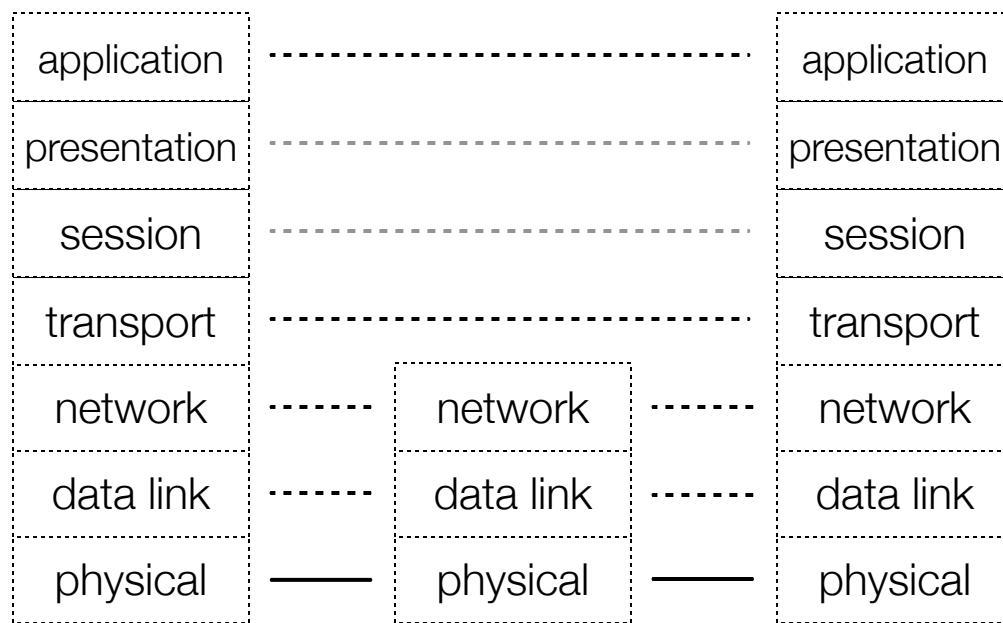

## Layer 5: session layer

- ▶ supposedly handles establishing, terminating application sessions
- ▶ RPC kind of fits in here

## Layer 6: presentation layer

- ▶ supposedly maps application-specific data units into a more network-neutral representation
- ▶ encryption (SSL) kind of fits in here

# The “application” layer

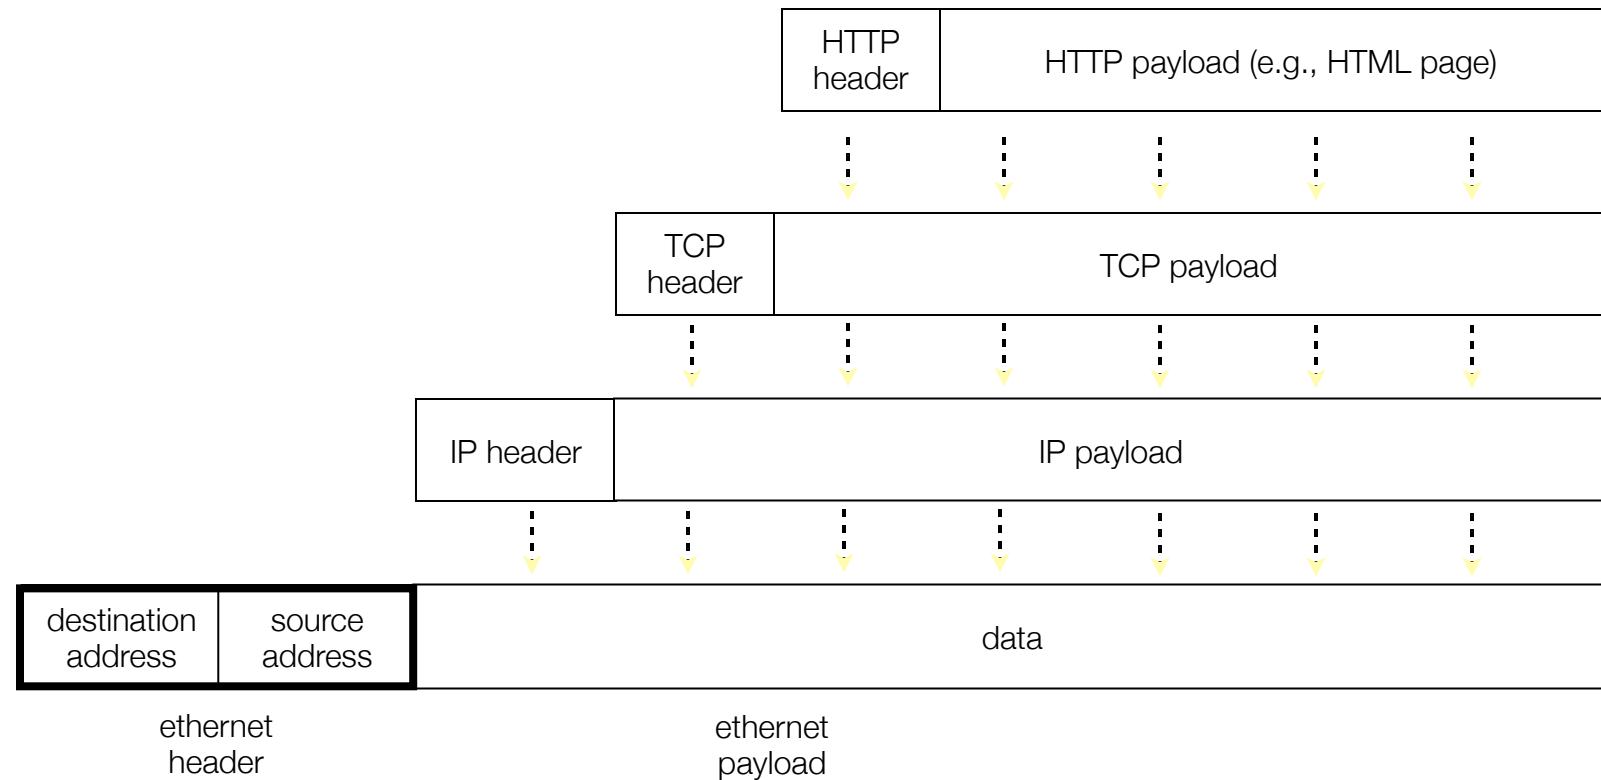

## Application protocols

- the format and meaning of messages between application entities
- e.g., HTTP is an application level protocol that dictates how web browsers and web servers communicate
  - ▶ HTTP is implemented on top of TCP streams

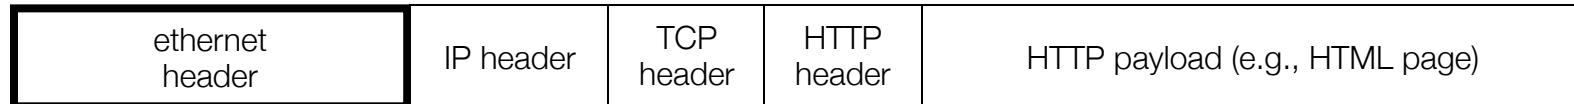

# The “application” layer

Packet encapsulation -- same as before!

# The “application” layer

Packet encapsulation -- same as before!

# The “application” layer

Popular application-level protocols:

- **DNS**: translates a DNS name (**www.google.com**) into one or more IP addresses (74.125.155.105, 74.125.155.106, ...)
  - ▶ a hierarchy of DNS servers cooperate to do this
- **HTTP**: web protocols
- **SMTP, IMAP, POP**: mail delivery and access protocols
- **ssh**: remote login protocol
- **bittorrent**: peer-to-peer, swarming file sharing protocol

See you on Wednesday!
