CSE 333
Lecture 7 - final C details

Hal Perkins

Department of Computer Science & Engineering

University of Washington

Administrivia

HW1 due in 3 days!

- some action on the discussion boards; well worth your while to peek!

- note: hashtable.c should not violate the modularity of ll.h

No exercises out before Friday

No class, office hours Wednesday: July 4

Sections this week: warmup for next project phase

Today's topics:

- finish a couple of examples from last time

- a few final C details

  ‣ header guards and other preprocessor tricks

  ‣ extern, static and visibility of symbols

  ‣ some topics for you to research on your own

an #include problem

What happens when we compile foo.c?

```
typedef void *LinkedList;

// more definitions below
                                    ll.h
```

```
#include "ll.h"
#include "ht.h"

int main(int argc,
            char **argv) {
  // ... do stuff here ...
  return 0;
}                              foo.c
```

```
                              ht.h
#include "ll.h"

typedef void *HashTable;

// A hypothetical function
LinkedList HTKeyList(HashTable t);
```

an #include problem

What happens when we compile foo.c?

```
bash$ gcc -Wall -g -o foo foo.c

In file included from ht.h:1,
                 from foo.c:2:
ll.h:1: error: redefinition of typedef 'LinkedList'
ll.h:1: note: previous declaration of 'LinkedList' was here
```

foo.c includes **ll.h** twice!

- 2nd time is indirectly via **ht.h**

- so, typedef shows up twice!

- *try using cpp to see this*

header guards

A commonly used C preprocessor trick to deal with this

- uses macro definition (#define)

- uses conditional compilation (#ifndef and #endif)

ll.h
```c
#ifndef _LL_H_
#define _LL_H_

typedef void *LinkedList;

// more definitions below

#endif  // _LL_H_
```

ht.h
```c
#ifndef _HT_H_
#define _HT_H_

#include "ll.h"

typedef void *HashTable;

// A hypothetical function
LinkedList HTKeyList(HashTable t);

#endif  // _HT_H_
```

Other preprocessor tricks

A way to deal with "magic constants"

```c
int globalbuffer[1000];

void circalc(float rad,
             float *circumf,
             float *area) {
  *circum = rad * 2.0 * 3.1415;
  *area = rad * 3.1415 * 3.1415;
}
```

bad code
(littered with magic constants)

```c
#define BUFSIZE 1000
#define PI 3.14159265359

int globalbuffer[BUFSIZE];

void circalc(float rad,
             float *circumf,
             float *area) {
  *circum = rad * 2.0 * PI;
  *area = rad * PI * PI;
}
```

better code

Macros

You can pass arguments to macros

```c
#define ODD(x) ((x) % 2 != 0)

void foo(void) {
   if ( ODD(5) )
     printf("5 is odd!\n");
}
```

cpp →

```c
void foo(void) {
   if ( ((5) % 2 != 0) )
     printf("5 is odd!\n");
}
```

Be careful of precedence issues; use parenthesis:

```c
#define ODD(x) ((x) % 2 != 0)
#define BAD(x) x % 2 != 0

ODD(5 + 1);

BAD(5 + 1);
```

cpp →

```c
((5 + 1) % 2 != 0);

5 + 1 % 2 != 0;
```

Conditional Compilation

You can change what gets compiled

```c
#ifdef TRACE
#define ENTER(f) printf("Entering %s\n", f);
#define EXIT(f)  printf("Exiting  %s\n", f);
#else
#define ENTER(f)
#define EXIT(f)
#endif

// print n
void pr(int n) {
  ENTER("pr");
  printf("n = %d\n", n);
  EXIT("pr");
}
```

ifdef.c

Defining Symbols

Besides #defines in the code, preprocessor values can be given on the gcc command

```
bash$ gcc -Wall -g -DTRACE -o ifdef ifdef.c
```

assert is controlled the same way - #define NDEBUG and asserts expand to "empty" (it's a macro)

```
bash$ gcc -Wall -g -DNDEBUG -o faster usesassert.c
```

Namespace problem

If I define a global variable named "counter" in foo.c, is it visible in bar.c?

- if you use **external linkage**: yes

  ‣ the name "**counter**" refers to the same variable in both files

  ‣ the variable is defined in one file, declared in the other(s)

  ‣ when the program is linked, the symbol resolves to one location

- if you use **internal linkage**: no

  ‣ the name "**counter**" refers to different variables in each file

  ‣ the variable must be defined in each file

  ‣ when the program is linked, the symbols resolve to two locations

External linkage

```c
#include <stdio.h>

// A global variable, defined and
// initialized here in foo.c.
// It has external linkage by
// default.
int counter = 1;

int main(int argc, char **argv) {
  printf("%d\n", counter);
  bar();
  printf("%d\n", counter);
  return 0;
}
```
foo.c

```c
#include <stdio.h>

// "counter" is defined and
// initialized in foo.c.
// Here, we declare it, and
// specify external linkage
// by using the extern
// specifier.
extern int counter;

void bar(void) {
  counter++;
  printf("(b): counter %d\n",
         counter);
}
```
bar.c

Internal linkage

```c
#include <stdio.h>

// A global variable, defined and
// initialized here in foo.c.
// We force internal linkage by
// using the static specifier.
static int counter = 1;

int main(int argc, char **argv) {
  printf("%d\n", counter);
  bar();
  printf("%d\n", counter);
  return 0;
}
```
foo.c

```c
#include <stdio.h>

// A global variable, defined and
// initialized here in bar.c.
// We force internal linkage by
// using the static specifier.
static int counter = 100;

void bar(void) {
  counter++;
  printf("(b): counter %d\n",
         counter);
}
```
bar.c

Some gotchas

Every global (variables and functions) is extern by default.

- unless you specify the static specifier, if some other module uses the same name, you'll end up with a collision!

    ‣ best case: compiler error

    ‣ worst case: stomp all over each other

- it's good practice to:

    ‣ use static to defend your globals (hide your private stuff!)

    ‣ place external (i.e., global) declarations in a module's header file

Extern, static functions

```c
// By using the static specifier, we are indicating
// that foo() should have internal linkage.  Other
// .c files cannot see or invoke foo().
static int foo(int x) {
  return x*3 + 1;
}

// Bar is "extern" by default.  Thus, other .c files
// could declare our bar() and invoke it.
int bar(int x) {
  return 2*foo(x);
}
```
bar.c

```c
#include <stdio.h>

extern int bar(int);

int main(int argc, char **argv) {
  printf("%d\n", bar(5));
  return 0;
}
```
main.c

Somebody should get fired

C has a second, different use for the word "static"

- to declare the extent of a local variable

- if you declare a static local variable, then:

  ‣ the storage for that variable is allocated when the program loads, in either the program's .data or .bss segment

  ‣ the variable retains its value across multiple function invocations!!!

    • DON'T DO THIS!!!! (unless you have a very, very, very good reason)

    (see static_extent.c for an example)

Additional C topics

Homework: teach yourself the following topics

- bit-level manipulation in C: **~ | & << >>**

- string library functions provided by the C standard library

  ‣ #include <string.h>

    • strlen( ), strcp( ), strdup( ), strcat( ), strcmp( ), strchr( ), strstr( ), ...

    • learn why **strncat** is safer (in the security sense) than **strcat**, etc.

  ‣ #include <stdlib.h> or #include <stdio.h>

    • atoi( ), atof( ), sprintf( ), sscanf( )

- **man** pages are your friend!

Additional C topics

Teach yourself:

- how to declare, define, and use a function that accepts a variable-lengthed number of arguments (varargs)

- unions and what they are good for

- what argc and argv are for in main (should be review by now)

```c
#include <stdio.h>

int main(int argc, char **argv) {
  int i;

  for (i = 0; i < argc, i++) {
    printf("%d: %s\n", i, argv[i]);
  }
  return 0;
}
```
argv.c

```
bash$ gcc -o argv argv.c
bash$ ./argv
0: ./argv
bash$ ./argv foo bar
0: ./argv
1: foo
2: bar
bash$
```

Additional C topics

Teach yourself:

- the difference between pre-increment (++v) and post-increment (v++)

- the meaning of the "register" storage class

  ‣ and why it is not used much these days

- harder: the meaning of the "volatile" storage class

  ‣ pages 91, 92 of CARM

At your leisure

To understand some of the beauty, lore, and craft of C:

- http://www-cs-students.stanford.edu/~blynn/c/

To understand the potential horrors of C:

- http://www0.us.ioccc.org/main.html

- e.g., http://www0.us.ioccc.org/2004/gavare.c

Exercise 1

Write a program that:

- prompts the user to input a string (use fgets( ))

  ‣ assume the string is a sequence of whitespace-separated integers

  ‣ e.g., "5555 1234 4 5543"

- converts the string into an array of integers

- converts an array of integers into an array of strings

  ‣ where each element of the string array is the binary representation of the associated integer

- prints out the array of strings

Exercise 2

Modify the linked list code from last lecture / exercise 1

- add static declarations to any internal functions you impemented in linkedlist.h

- add a header guard to the header file

- write a Makefile

  ‣ use Google to figure out how to add rules to the Makefile to produce a library (liblinkedlist.a) that contains the linked list code

See you on Friday!
