CSE 333 Lecture 16 -- networks

Hal Perkins

Department of Computer Science & Engineering University of Washington

CSE333 lec 16 networks // 02-22-16 // Perkins

Administrivia

HW3 due Thursday night

Today - overview of networking

Then - client-side and server-side TCP sockets

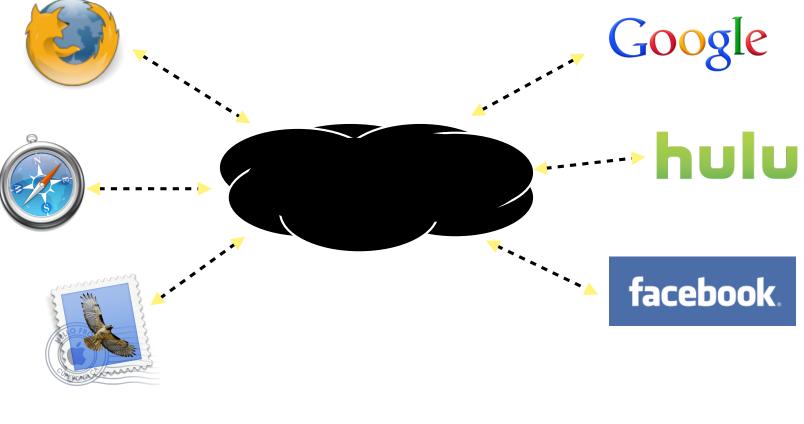

Rest of the quarter

HW4 out Friday; due last Thur. of the quarter (+ late days if you have/need them)

A few more exercises, but none due this week - next one out Thursday after sections, due the following Monday

Final exam Wed. March 16, 2:30-4:20. Review session late the previous afternoon if there is demand for it.

Networks from 10,000ft

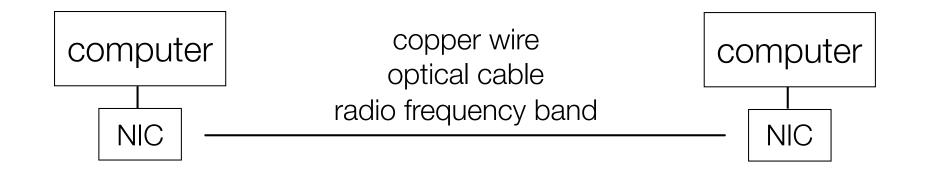

clients

The "physical" layer

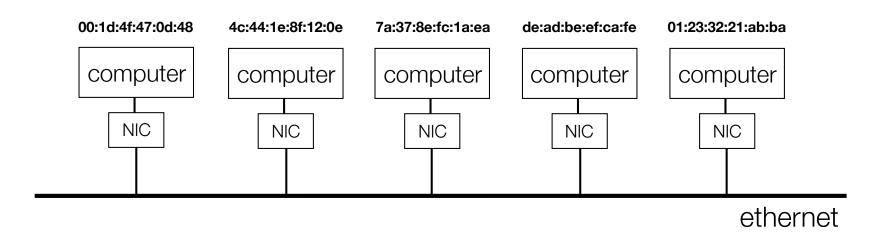

Individual bits are modulated onto a wire or transmitted over radio physical layer specifies how bits are encoded at a signal level e.g., a simple spec would encode "1" as +1V, "0" as -1V

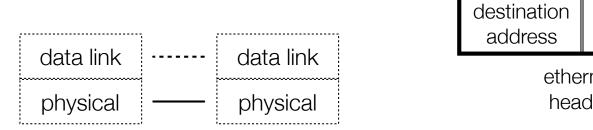

The "data link" layer

Multiple computers on a LAN contend for the network medium media access control (MAC) specifies how computers cooperate link layer also specifies how bits are packetized and NICs are addressed

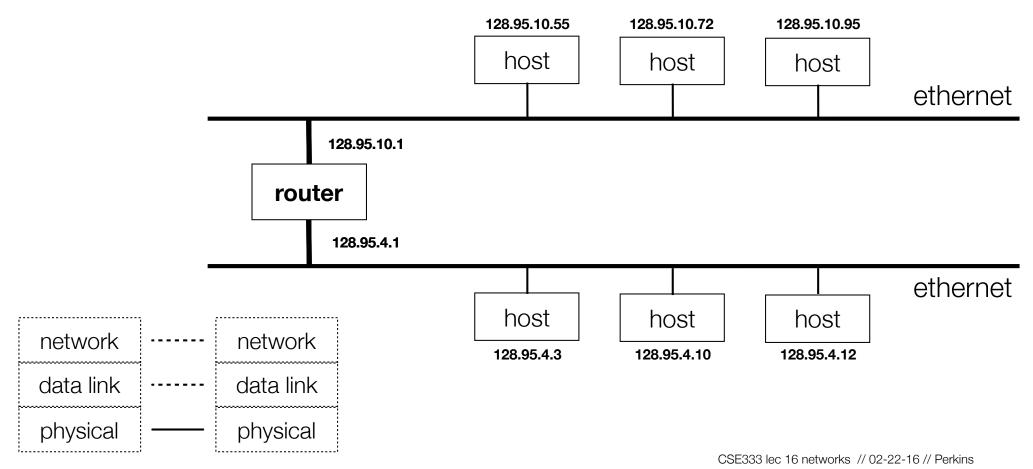

The "network" layer (IP)

The Internet Protocol (IP) routes packets across multiple networks

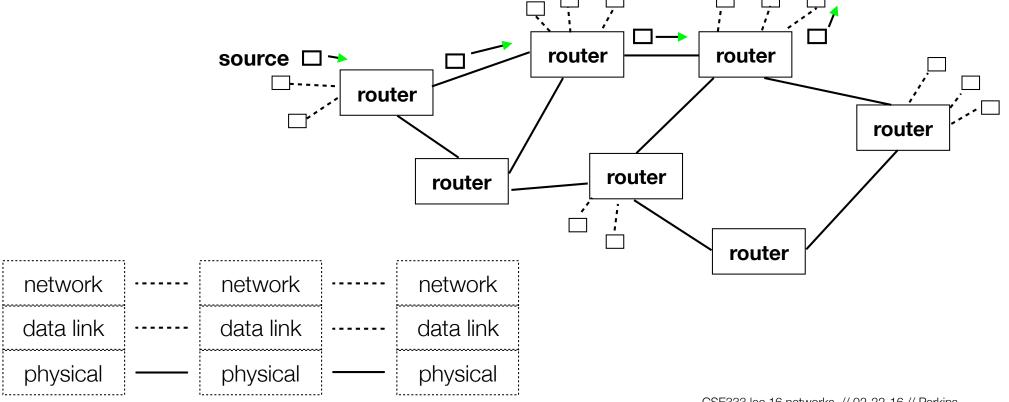

- every computer has a unique Internet address (IP address)
- individual networks are connected by routers that span networks

The "network" layer (IP)

Protocols to:

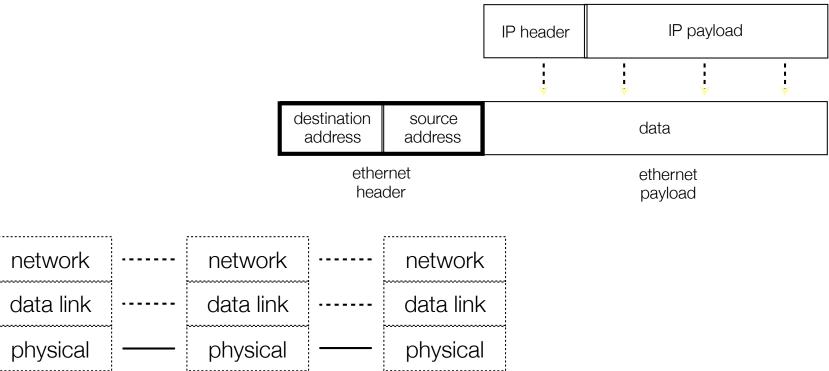

- let a host find the MAC address of an IP address on the same network
- let a router learn about other routers and figure out how to get IP packets one step closer to their destination destination

The "network" layer (IP)

Packet encapsulation

- an IP packet is encapsulated as the payload of an Ethernet frame
- as IP packets traverse networks, routers pull out the IP packet from an ethernet frame and plunk it into a new one on the next network

The "transport" layer (TCP, UDP)

TCP

the "transmission control protocol"

provides apps with reliable, ordered, congestion-controlled byte streams

fabricates them by sending multiple IP packets, using sequence numbers to detect missing packets, and retransmitting them

a single host (IP address) can have up to 65,535 "ports"

kind of like an apartment number at a postal address

transport	······			transport
network		network		network
data link		data link		data link
physical		physical		physical

The "transport" layer (TCP, UDP)

TCP

useful analogy: how would you send a book by mail via postcards?

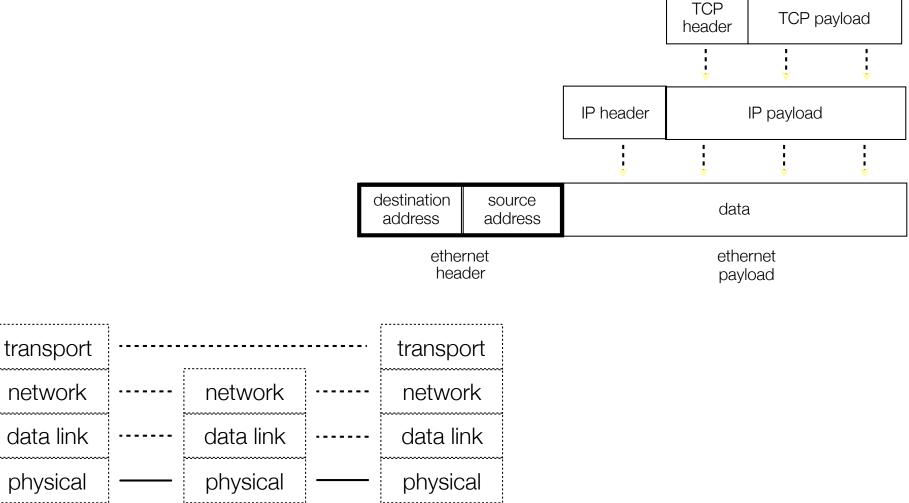

split the book into multiple postcards, send each one by one, including sequence numbers that indicate the assembly order

receiver sends back postcards to acknowledge receipt and indicate which got lost in the mail

	:			
transport				transport
network		network		network
data link		data link		data link
physical		physical		physical

The "transport" layer (TCP)

Packet encapsulation -- same as before!

The "transport" layer (TCP)

Applications use OS services to establish TCP streams the "Berkeley sockets" API -- a set of OS system calls clients **connect()** to a server IP address + application port number servers **listen()** for and **accept()** client connections clients, servers **read()** and **write()** data to each other

transport				transport
network		network		network
data link		data link		data link
physical		physical		physical

The "transport" layer (UDP)

UDP

the "user datagram protocol"

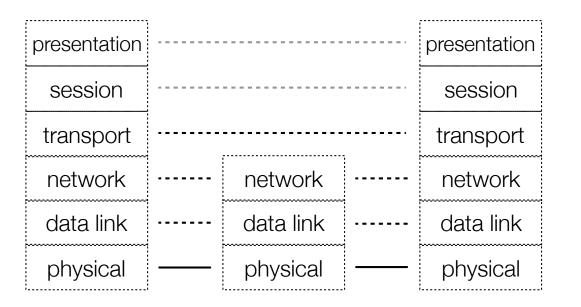

provides apps with unreliable packet delivery

UDP datagrams are fragmented into multiple IP packets

UDP is a really thin, simple layer on top of IP

 transport	 	transport
 network	 network	 network
data link	 data link	 data link
physical	 physical	 physical

The (mostly missing) layers 5,6

Layer 5: session layer

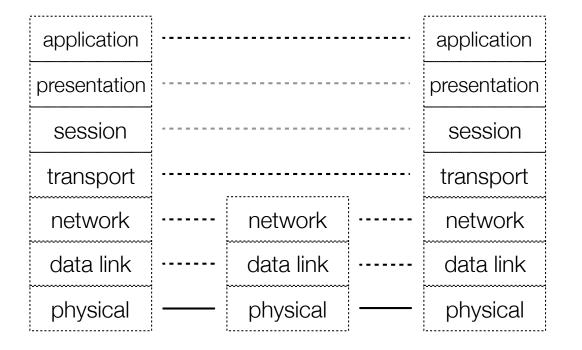

supposedly handles establishing, terminating application sessions

RPC kind of fits in here

Layer 6: presentation layer

supposedly maps applicationspecific data units into a more network-neutral representation

encryption (SSL) kind of fits in here

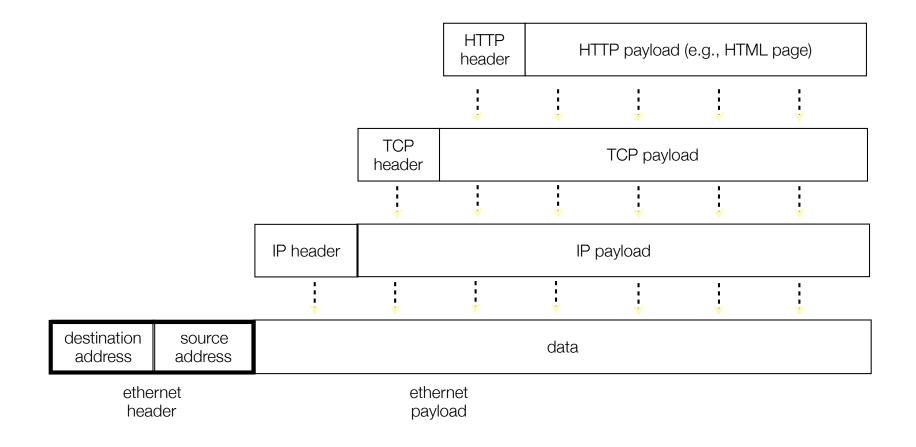

Application protocols

the format and meaning of messages between application entities

e.g., HTTP is an application level protocol that dictates how web browsers and web servers communicate

HTTP is implemented on top of TCP streams

Packet encapsulation -- same as before!

Packet encapsulation -- same as before!

ethernet header	IP header	TCP header	HTTP header	HTTP payload (e.g., HTML page)
--------------------	-----------	---------------	----------------	--------------------------------

Popular application-level protocols:

DNS: translates a DNS name (**www.google.com**) into one or more IP addresses (74.125.155.105, 74.125.155.106, ...)

a hierarchy of DNS servers cooperate to do this

HTTP: web protocols

SMTP, **IMAP**, **POP**: mail delivery and access protocols

ssh: remote login protocol

bittorrent: peer-to-peer, swarming file sharing protocol

See you on Wednesday!
