CSE 333

Lecture 6 - final C details

Hal Perkins

Department of Computer Science & Engineering

University of Washington

Administrivia 1

Exercise 5 (fix and modularize buggy program) posted after section yesterday. Due Monday morning

HW1 still due next Thursday

Administrivia 2

HW1, due Thursday night

- Watch that hashtable.c doesn't violate the modularity of ll.h
- Watch for pointers to local (stack) variables - don't store in persistent data
- What do you do if one of the test_suite tests fails and it's not obvious why?
- Hints: segfault? use gdb (bt, …); make small tests; breakpoints in Verify333
- Suggestion from past graders: clean up the "to do" comments, but if you can, leave the "step 1", "step 2" markers so they can find things quickly
- Extra credit: if you add unit tests, put them in a new file and adjust the makefile
- Quiz: what is the late day policy?
- If you decide to use a late day, don't tag hw1-final until you are really ready

Administrivia - Code Quality

Code quality ("style") **really** matters - and not just for homework

Rule #0: reader's time is ***much*** more important than writer's

Good comments are essential, clarity/understandibility is critical

Good comments ultimately save writer's time too!

Rule #1: match existing code

Rule #2: use tools. examples:

Compiler warnings: just fix them!

clint style warnings: fix most of them; be sure you understand anything you don't fix and can justify it (ok to have a type as malloc parameter or use readdir, not ok to have tabs instead of spaces or magic numbers instead of #define, etc., ...)

valgrind warnings: fix all of them unless you know why it's not an error (example: reading/printing uninitialized bytes in a debugging tool)

Agenda

Today's topics:

- a few final C details
  - header guards and other preprocessor tricks
  - extern, static and visibility of symbols
  - some topics for you to research on your own

an #include problem

What happens when we compile foo.c?

```
struct pair { int a, b; };
```

pair.h

```
#include "pair.h"
#include "util.h"

int main(int argc,
         char **argv) {
  // ... do stuff here ...
  return 0;
}
```

foo.c

util.h

```
#include "pair.h"

// a useful function
struct pair *make_pair(int a, int b);
```

an #include problem

What happens when we compile foo.c?

```
bash$ gcc -Wall -g -o foo foo.c

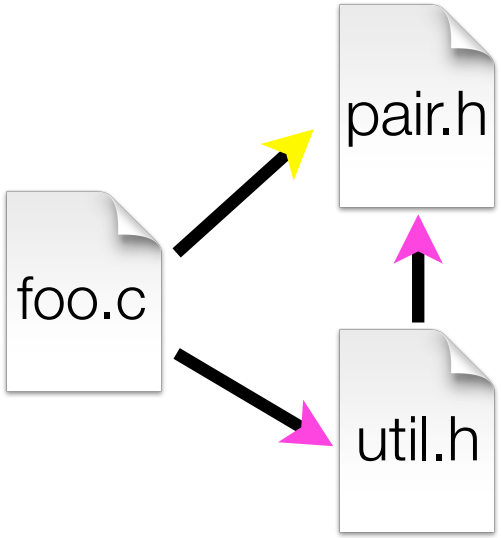
In file included from foo.c:2:
In file included from ./util.h:1:
./pair.h:1:8: error: redefinition of 'pair'
struct pair { int a, b; };
       ^
./pair.h:1:8: note: previous definition is here
```

foo.c includes **pair.h** twice!

2nd time is indirectly via **util.h**

so, struct def shows up twice!

try using cpp to see this



header guards

A commonly used C preprocessor trick to deal with this

- uses macro definition (#define)
- uses conditional compilation (#ifndef and #endif)

pair.h

```
#ifndef _PAIR_H_
#define _PAIR_H_

struct pair { int a, b; };

#endif  // _PAIR_H_
```

util.h

```
#ifndef _UTIL_H_
#define _UTIL_H_

#include "pair.h"

// a useful function
struct pair *make_pair(int a, int b);

#endif  // _UTIL_H_
```

Other preprocessor tricks

A way to deal with “magic constants”

```
int globalbuffer[1000];

void circalc(float rad,
             float *circumf,
             float *area) {
  *circumf = rad * 2.0 * 3.1415;
  *area = rad * 3.1415 * 3.1415;
}
```

bad code
(littered with magic constants)

```
#define BUFSIZE 1000
#define PI 3.14159265359

int globalbuffer[BUFSIZE];

void circalc(float rad,
             float *circumf,
             float *area) {
  *circumf = rad * 2.0 * PI;
  *area = rad * PI * PI;
}
```

better code

Macros

You can pass arguments to macros

```
#define ODD(x) ((x) % 2 != 0)

void foo() {
   if ( ODD(5) )
     printf("5 is odd!\n");
}
```

```
void foo() {
   if ( ((5) % 2 != 0) )
     printf("5 is odd!\n");
}
```

Be careful of precedence issues; use parenthesis:

```
#define ODD(x) ((x) % 2 != 0)
#define WEIRD(x) x % 2 != 0

ODD(5 + 1);

WEIRD(5 + 1);
```

```
((5 + 1) % 2 != 0);

5 + 1 % 2 != 0;
```

Conditional Compilation

You can change what gets compiled

```
#ifdef TRACE
#define ENTER(f) printf("Entering %s\n", f);
#define EXIT(f)  printf("Exiting  %s\n", f);
#else
#define ENTER(f)
#define EXIT(f)
#endif

// print n
void pr(int n) {
  ENTER("pr");
  printf("n = %d\n", n);
  EXIT("pr");
}
```

ifdef.c

Defining Symbols

Besides #defines in the code, preprocessor values can be given on the gcc command

```
bash$ gcc -Wall -g -DTRACE -o ifdef ifdef.c
```

assert is controlled the same way - #define NDEBUG and asserts expand to “empty” (it’s a macro - see assert.h)

```
bash$ gcc -Wall -g -DNDEBUG -o faster usesassert.c
```

Namespace problem

If I define a global variable named "counter" in foo.c, is it visible in bar.c?

- if you use **external linkage**: yes
  - the name "**counter**" refers to the same variable in both files
  - the variable is defined in one file, declared in the other(s)
  - when the program is linked, the symbol resolves to one location
- if you use **internal linkage**: no
  - the name "**counter**" refers to different variables in each file
  - the variable must be defined in each file
  - when the program is linked, the symbols resolve to two locations

External linkage

```
#include <stdio.h>

// A global variable, defined and
// initialized here in foo.c.
// It has external linkage by
// default.
int counter = 1;

int main(int argc, char **argv) {
  printf("%d\n", counter);
  bar();
  printf("%d\n", counter);
  return 0;
}
```

foo.c

```
#include <stdio.h>

// "counter" is defined and
// initialized in foo.c.
// Here, we declare it, and
// specify external linkage
// by using the extern
// specifier.
extern int counter;

void bar() {
  counter++;
  printf("(b): counter %d\n",
         counter);
}
```

bar.c

Internal linkage

```
#include <stdio.h>

// A global variable, defined and
// initialized here in foo.c.
// We force internal linkage by
// using the static specifier.
static int counter = 1;

int main(int argc, char **argv) {
  printf("%d\n", counter);
  bar();
  printf("%d\n", counter);
  return 0;
}
```

foo.c

```
#include <stdio.h>

// A global variable, defined and
// initialized here in bar.c.
// We force internal linkage by
// using the static specifier.
static int counter = 100;

void bar() {
  counter++;
  printf("(b): counter %d\n",
         counter);
}
```

bar.c

Some gotchas

Every global (variables and functions) is extern by default

- unless you write the static specifier, if some other module uses the same name, you'll end up with a collision!
  - best case: compiler (or linker) error
  - worst case: stomp all over each other
- it's good practice to:
  - use static to defend your globals (hide your private stuff!)
  - place external (i.e., global) declarations in a module's header file

Extern, static functions

```
// By using the static specifier, we are indicating
// that foo() should have internal linkage.  Other
// .c files cannot see or invoke foo().
static int foo(int x) {
  return x*3 + 1;
}

// Bar is "extern" by default.  Thus, other .c files
// could declare our bar() and invoke it.
int bar(int x) {
  return 2*foo(x);
}
```

bar.c

```
#include <stdio.h>

extern int bar(int);

int main(int argc, char **argv) {
  printf("%d\n", bar(5));
  return 0;
}
```

main.c

Somebody should get fired

C has a second, different use for the word “static”

- to declare the extent of a local variable
- if you declare a static local variable, then:
  - the storage for that variable is allocated when the program loads, in either the program’s .data or .bss segment
  - the variable retains its value across multiple function invocations

(see static_extent.c for an example)

Additional C topics

Teach yourself

- bit-level manipulation in C (cf CSE 351): **~ | & << >>**
- string library functions provided by the C standard library
  - #include <string.h>
    - strlen( ), strcp( ), strdup( ), strcat( ), strcmp( ), strchr( ), strstr( ), ...
    - learn why **strncat** is safer (in the security sense) than **strcat**, etc.
  - #include <stdlib.h> or #include <stdio.h>
    - atoi( ), atof( ), sprintf( ), sscanf( )
- **man** pages are your friend!

Additional C topics

Teach yourself

- the syntax for function pointers, including passing as args
- how to declare, define, and use a function that accepts a variable-lengthed number of arguments (varargs)
- unions and what they are good for
- what argc and argv are for in main

```
#include <stdio.h>

int main(int argc, char **argv) {
  int i;

  for (i = 0; i < argc, i++) {
    printf("%d: %s\n", i, argv[i]);
  }
  return 0;
}
```

argv.c

```
bash$ gcc -o argv argv.c
bash$ ./argv
0: ./argv
bash$ ./argv foo bar
0: ./argv
1: foo
2: bar
bash$
```

Additional C topics

Teach yourself:

- the difference between pre-increment (++v) and post-increment (v++)
- the meaning of the “register” storage class
  - Might see it in code, but compilers often ignore it these days since they usually do a better job that way
- harder: the meaning of the “volatile” storage class
  - pages 91, 92 of CARM, much more precise in C11

Exercise 1

Write a program that:

- prompts the user to input a string (use fgets( ))
  - assume the string is a sequence of whitespace-separated integers
  - e.g., “5555 1234 4 5543”
- converts the string into an array of integers
- converts an array of integers into an array of strings
  - where each element of the string array is the binary representation of the associated integer
- prints out the array of strings

Exercise 2

Modify the linked list code from last lecture / exercise 1

- add static declarations to any internal functions you impemented in linkedlist.h
- add a header guard to the header file
- write a Makefile
  - use Google to figure out how to add rules to the Makefile to produce a library (liblinkedlist.a) that contains the linked list code

See you on Monday!

(But wait!!! There's more.…)
