Build Tools (make)
CSE 333 Autumn 2018

Instructor:  Hal Perkins

Teaching Assistants:
Tarkan Al-Kazily  Renshu Gu  Travis McGaha
Harshita Neti  Thai Pham  Forrest Timour
Soumya Vasisht  Yifan Xu
Lecture Outline

- Make and Build Tools
make

- **make** is a classic program for controlling what gets (re)compiled and how
  - Many other such programs exist (*e.g.* ant, maven, IDE “projects”)

- **make** has tons of fancy features, but only two basic ideas:
  1. Scripts for executing commands
  2. Dependencies for avoiding unnecessary work

- To avoid “just teaching **make** features” (boring and narrow), let’s focus more on the concepts...
Building Software

- Programmers spend a lot of time “building”
  - Creating programs from source code
  - Both programs that they write and other people write

- Programmers like to automate repetitive tasks
  - Repetitive: `gcc -Wall -g -std=c11 -o widget foo.c bar.c baz.c`
    - Retype this every time: 😥
    - Use up-arrow or history: 😞 (still retype after logout)
    - Have an alias or bash script: 😊
    - Have a Makefile: 😊 (you’re ahead of us)
“Real” Build Process

- On larger projects, you can’t or don’t want to have one big (set of) command(s) that redoes everything every time you change anything:
  1) If gcc didn’t combine steps for you, you’d need to preprocess, compile, and link on your own (along with anything you used to generate the C files)
  2) If source files have multiple outputs (e.g. javadoc), you’d have to type out the source file name(s) multiple times
  3) You don’t want to have to document the build logic when you distribute source code
  4) You don’t want to recompile everything every time you change something (especially if you have $10^5$-$10^7$ files of source code)

- A script can handle 1-3 (use a variable for filenames for 2), but 4 is trickier
Recompilation Management

- The “theory” behind avoiding unnecessary compilation is a *dependency dag* (directed, acyclic graph)

- To create a target $t$, you need sources $s_1, s_2, \ldots, s_n$ and a command $c$ that directly or indirectly uses the sources
  - It $t$ is newer than every source (file-modification times), assume there is no reason to rebuild it
  - Recursive building: if some source $s_i$ is itself a target for some other sources, see if it needs to be rebuilt...
  - Cycles “make no sense”!
Theory Applied to C

Compiling a `.c` creates a `.o` – the `.o` depends on the `.c` and all included files (`.h`, recursively/transitively)
Theory Applied to C

- Compiling a `.c` creates a `.o` – the `.o` depends on the `.c` and all included files (`.h`, recursively/transitively)
- An archive (library, `.a`) depends on included `.o` files
Theory Applied to C

- Compiling a `.c` creates a `.o` – the `.o` depends on the `.c` and all included files (`.h`, recursively/transitively)
- An archive (library, `.a`) depends on included `.o` files
- Creating an executable (“linking”) depends on `.o` files and archives
  - Archives linked by `-L<path> -l<name>`
    (e.g. `-L. -lfoo to get libfoo.a from current directory`)
Theory Applied to C

- If one `.c` file changes, just need to recreate one `.o` file, maybe a library, and re-link

- If a `.h` file changes, may need to rebuild more

- Many more possibilities!
make Basics

- A makefile contains a bunch of **triples**:
  ```
  target: sources
  ← Tab → command
  ```
  - Colon after target is **required**
  - Command lines must start with a **TAB**, NOT SPACES
  - Multiple commands for same target are executed **in order**
    - Can split commands over multiple lines by ending lines with "\"

- **Example:**
  ```
  foo.o: foo.c foo.h bar.h
  gcc -Wall -o foo.o -c foo.c
  ```
Using make

```bash
make -f <makefileName> target
```

- **Defaults:**
  - If no `-f` specified, use a file named `Makefile`
  - If no `target` specified, will use the first one in the file
  - Will interpret commands in your default shell
    - Set `SHELL` variable in makefile to ensure

- **Target execution:**
  - Check each source in the source list:
    - If the source is a target in the Makefile, then process it recursively
    - If some source does not exist, then error
    - If any source is newer than the target (or target does not exist), run command (presumably to update the target)
make Variables

- You can define variables in a makefile:
  - All values are strings of text, no “types”
  - Variable names are case-sensitive and can’t contain ‘:’, ‘#’, ‘=’, or whitespace

- Example:
  ```
  CC = gcc
  CFLAGS = -Wall -std=c11
  foo.o: foo.c foo.h bar.h
        $(CC) $(CFLAGS) -o foo.o -c foo.c
  ```

- Advantages:
  - Easy to change things (especially in multiple commands)
  - Can also specify on the command line (CC=clang FLAGS=-g)
More Variables

- It’s common to use variables to hold list of filenames:

```bash
OBJFILES = foo.o bar.o baz.o
widget:  $(OBJFILES)
        gcc -o widget $(OBJFILES)
clean:
        rm $(OBJFILES) widget *~
```

- `clean` is a convention

  - Remove generated files to “start over” from just the source
  - It’s “funny” because the target doesn’t exist and there are no sources, but it works because:
    - The target doesn’t exist, so it must be “remade” by running the command
    - These “phony” targets have several uses, such as “all”...
“all” Example

all: prog B.class someLib.a
    # notice no commands this time

    prog: foo.o bar.o main.o
         gcc -o prog foo.o bar.o main.o

    B.class: B.java
             javac B.java

    someLib.a: foo.o baz.o
               ar r foo.o baz.o

    foo.o: foo.c foo.h header1.h header2.h
           gcc -c -Wall foo.c

    # similar targets for bar.o, main.o, baz.o, etc...
Makefile Example

- “talk” program (find files on web with lecture slides)

main.c  speak.h  speak.c  shout.h  shout.c
Revenge of the Funny Characters

- **Special variables:**
  - `@$` for target name
  - `@$^` for all sources
  - `@$<` for left-most source
  - Lots more! – see the documentation

- **Examples:**

```plaintext
# CC and CFLAGS defined above
widget:
  foo.o
  bar.o
$(CC) $(CFLAGS) -o @$ @$^  
foo.o:
  foo.c
  foo.h
  bar.h
$(CC) $(CFLAGS) -c @$<
```
And more...

- There are a lot of “built-in” rules – see documentation
- There are “suffix” rules and “pattern” rules
  - Example: .class: .java
    javac $<  # we need the $< here
- Remember that you can put any shell command – even whole scripts!
- You can repeat target names to add more dependencies
- Often this stuff is more useful for reading makefiles than writing your own (until some day...)
Extra Exercise #1

- Modify the linked list code from Lecture 5 Extra Exercise #1
  - Add static declarations to any internal functions you implemented in `linkedlist.h`
  - Add a header guard to the header file
  - Write a Makefile
    - Use Google to figure out how to add rules to the `Makefile` to produce a library (`liblinkedlist.a`) that contains the linked list code
