# 12sp

### Problem 1: Multiple Choice Madness (24 points)

Circle exactly one answer for each of the following questions:

i. It is possible for C code to determine the endian-ness of the underlying CPU.

a) true b) false

- ii. In C, a pointer is a variable that contains an address. If you add 2 to a pointer, then:
  - a) the resulting value is the address plus 2
  - b) the resulting value depends on what value the pointer points to

### c) the resulting value depends on the type of the pointer

- d) a segmentation fault is thrown
- iii. When you pass a struct as an argument to a C function, then:
  - a) the struct is passed by value (i.e., a copy of the struct is made, including copying each field in the struct))
  - b) the struct is passed by reference (i.e., a pointer to the struct is passed)
  - c) a compiler error is thrown, since you cannot pass structs as arguments
  - d) what happens depends on the type of fields in the struct
- iv. When you pass an array as an argument to a C function, then:
  - a) the array elements are passed by value (i.e., a copy of the array is made, including copying each element of the array)
  - b) since arrays are really just pointers, a pointer to the first element of the array is passed and no array elements are copied
  - c) a compiler error is thrown, since you cannot pass arrays as arguments
  - d) what happens depends on the type of the array

- v. The purpose of a header guard is to:
  - a) prevent more than one .c file from including a particular .h file
  - b) prevent the header file from being included indirectly, as a side-effect of including some other .h file that includes it
  - c) document the contents and purpose of the header file

# d) prevent the header file from being included twice, directly or indirectly

- vi. A C++ reference:
  - a) serves as an alternative name for an object or variable (i.e., is an alias)
  - b) serves as a pointer to an object or variable
  - c) cannot be used as a parameter of a function
  - d) cannot be passed as an argument to a function
- vii. What does "const" in the following code imply?

#### void foo (const int \*x) { ... }

- a) the value of the pointer "x" cannot be changed inside the function foo
- b) the function foo cannot have any side-effects
- c) nothing; const in this case has no effect

# d) the value that the pointer "x" points to cannot be changed inside the function foo

viii. What does "const" in the following code imply?

#### void Foo::bar (int \*x) { ... } const;

- a) the method bar() cannot mutate any of its parameters
- b) the method bar() cannot have any side-effects at all

### c) the method bar() cannot mutate any of Foo's state

d) the method bar() can only invoke const-y functions and methods

- ix. Which of the following box and arrow diagrams correctly represents the following code?
  - int x = 5; int \*y = &x; int &z = x; int \*w = &z;

- **x.** The destructor of an object that is heap-allocated:
  - a) is invoked when the function in which it is allocated returns
  - b) is never invoked
  - c) must be invoked manually
  - d) is invoked when somebody uses "delete" to deallocate the object

### **xi.** A vtable:

a) exists for each class, and contains a function pointer for each method in the class

# b) exists for each class, and contains a function pointer for each virtual method in the class

- c) exists for each object instance, and contains a function pointer for each method in the object's class
- d) exists for each object instance, and contains a function pointer for each virtual method in the object's class
- **xii.** Slicing occurs when:

### a) the value of a derived class is assigned to an instance of a base class

- b) a pointer to a derived class is cast to, and assigned to, a pointer to a base class
- c) an N-element array is assigned to an M-element array, where M<N
- d) an element is deleted from a std::vector

### CSE 333 Final Exam June 10<sub>10</sub>, 11111011111<sub>2</sub> Sample Solution

**Question 1.** (20 points) A bit of C++ hacking – STL version The question that is a lot longer than the answer. It's a social media world and Twitter wants you to digest some data that they have. Write a program that reads input from stdin. Each line in the input contains two strings: first, the name of a follower and second the name of a person they follow. So, for instance, an input line of text containing

bob alice

means that "bob" follows "alice". The output should contain one line for each person who has one or more followers and contain the person's name and number of followers. Example: if alice has 12 followers and ed has 3,415, the output should be:

alice 12 ed 3415

The names in the output should be sorted (which is the default order in which an iterator for maps access the data).

You should use a C++ STL map container to accumulate the data. Here is some brief reference information about maps:

- A STL map is a collection of Pair objects. If p is a Pair, then p.first and p.second denote its two components. If the Pair is stored in a map, then p.first is the key and p.second is the associated value.
- As with any STL container, if m is a map, m.begin() and m.end() return iterator values that might be useful. For a map, these iterators refer to the Pair objects in the map.
- If it is an iterator, then \*it can be used to reference the item it currently points to, and ++it will advance it to the next item, if any.
- Some useful operations on all STL containers, including map:
  - o c.clear() remove all elements from c
  - o c.size() return number of elements in c
  - o c.empty() true if number of elements in c is 0, otherwise false
- Some additional operations on maps:
  - o m.insert(x) add copy of x to m (a key-value pair for a map)
  - o m[k] can be used to access the value associated with key k. If m[k] is read and has has never been accessed before, then a <key,value> Pair is added to the map with k as the key and with a value created by the default constructor for the value type (0 or nullptr for primitive types).
- You are free to use the C++11 auto keyword, C++11-style for-loops for iterating through containers, and any other features of standard C++11, but you are not required to use these.

Write your answer on the next page. You may remove this page for reference while working if you wish.

### CSE 333 Final Exam June 10<sub>10</sub>, 11111011111<sub>2</sub> Sample Solution

Question 1. (cont.) Write your program to read and summarize the Twitter follower data below. You do not need to write #includes – assume that these are already provided. You also may assume that input operations succeed until there is no more data. You do not need to do error checking beyond that. To simplify things, use standard C++ input and output (cin and cout).

Here is one fairly simple solution. There are, of course, many others that would work. In particular, there are lots of ways to write the loop that iterates through the map to print the results (use explicit iterators instead of the C++11 for loop, use value copy instead of references, write explicit type declarations instead of auto, etc.). If done correctly, any of those solutions received credit.

```
int main() {
    // read and accumulate lists of followers
    string follower, followed;
    map<string,int> who;
    while (cin >> follower >> followed) {
        who[followed] += 1;
    }
    // print statistics
    for (const auto &person: who) {
        cout << person.first << " " << person.second << endl;
    }
    return 0;
}</pre>
```

## 14wi

**Question 7.** (12 points) Sockets and packets, oh my! Circle true or false for each of the following statements.

true	false	TCP guarantees reliable delivery of the packets that make up a stream, assuming that the socket doesn't fail because of an I/O error.
true (	false	IP guarantees reliable delivery of packets, assuming that the socket doesn't fail because of an I/O error.
		Packets are delivered on a "best effort" basis, but may be dropped along the way due to congestion, routing problems, or other issues.
true (	false	Given a particular hostname (like www.amazon.com), getaddrinfo() will return a single IP address corresponding to that name. getaddrinfo() returns a list of possible addresses.
true	false	A single server machine can handle connection requests sent to multiple IP addresses.
true (	false	The listen function returns a file descriptor number for a socket that a server can use to exchange data with the connected client machine. <b>listen instructs the operating system to queue up incoming</b> <b>connection requests from clients on a particular socket file descriptor.</b> <b>accept returns a file descriptor the server can use to exchange</b> <b>messages with clients.</b>
true (	false	A router stores information about the complete path needed to send a IP packet to its destination. <b>Routers generally know which of their neighbors would be a good bet</b> <b>to forward a packet on the next hop towards its destination, but they</b> <b>generally do not have detailed information beyond that.</b>

## 15su CSE 333 Final Exam August 21, 2015 Sample Solution

**Question 2.** (16 points) Smart pointers. The following program creates a short linked list. But it leaks memory because it never deletes any of the heap-allocated data.

Fix this program so it has no memory leaks. However, you may not alter what the program does, you may not replace pointers to data with copies of the data, and you may not insert any delete statements. Instead, you should fix the leaks by changing the code to use smart pointers appropriately instead of regular pointers. Cross out existing code and write new code as needed. Legibility is a big help – please write clearly.

### Changes needed shown in bold below.

```
#include <iostream> // needed only for printing list
#include <memory> // smart pointers (for solution)
using namespace std;
struct Node {
  unique ptr<int> val ; // ptr to node's data on heap
  shared ptr<Node> next ; // next node in list or nullptr if none
};
int main() {
  // create list
                                              or list->val_.reset(new int(17));
  shared_ptr<Node> list( new Node() );
  list->val = unique ptr<int>( new int(17) );
  shared ptr<Node> p( new Node() );
  p->val = unique_ptr<int>( new int(42) );
  p->next = nullptr;
                                              > or p->val .reset(new int(42));
  list->next = p;
  // print list
  for (auto n = list; n != nullptr; n = n->next )
    cout << *(n->val ) << " ";</pre>
  cout << endl;</pre>
  return 0;
}
```

Notes: The payload (val\_) pointer could have also been a shared\_ptr, but since each node has the only pointer to its data a unique\_ptr is more efficient. Pointers to the list nodes need to be shared\_ptrs, however, to allow for assignments.

There are other ways to solve the problem and correct solutions received credit provided they only modified the program to use smart pointers and did not change it otherwise.

## 14wi

**Question 2.** (19 points) The following header file defines a class that holds a pair of integers and includes a constructor and functions for accessing the values.

```
#ifndef _Pair_h_
#define Pair h
template <class T>
class Pair {
public:
  // Construct a Pair with given first and second values
  Pair(int T first, int T second)
      : first (first), second (second) { }
  // accessors: return first and second items from Pair
  int T first() const { return first ; }
  int T second() const { return second ; }
private:
  // instance variables
  int T first ;
  int T second ;
};
#endif // _Pair_h_
```

(a) (6 points) We would like to generalize this class so it can be used to store any pairs of values as long as the values have the same type (i.e., pairs of ints or pairs of strings, etc.)

Show the changes needed to make this a generic class where the element type is a type parameter instead of int. You should write your changes and additions in the above code. Hint: you'll need to start by adding template <class T> (or template <typename T>, which is equivalent) at the beginning of the class definition.

### (Changes shown in green bold above)

(continued on the next page)

### CSE 333 Final Exam Sample Solution 3/19/14

**Question 2. (cont.)** We would now like to add an addition (+) operator to the generic Pair class on the previous page. If (a,b) and (c,d) are Pair values, then (a,b)+(c,d) should yield a new Pair containing (a+c, b+d). Neither of the original Pair objects should be modified. You do not need to check that addition (+) is defined on the items stored in a Pair – that is handled for you by the compiler when the addition operator is used.

(b) (5 points) Write the function declaration (not the implementation) to be added to the header file Pair.h for the new operator+.

```
// return a new Pair that is the element-wise sum of
// this and other
```

```
Pair<T> operator+(const Pair<T> &other) const;
```

(You did not need to supply a comment, although that would be expected in a real project.)

(c) (8 points) Give the code to implement this new addition operator as it would appear in a separate file Pair.cc containing definitions of functions not implemented in Pair.h. Hint: the implementation needs to begin with template <class T>.

(The file containing this template would have to #include the Pair.h header, and client code would need to include both the header and implementation to use it. That wouldn't make any difference in how the template is written and was not considered while grading.)

## 17au CSE 333 Final Exam December 13, 2017 Sample Solution

**Question 3.** (32 points) The usual, demented, dreaded virtual function madness. Consider the following program, which, when appropriate code is inserted in the blank space in main, does compile and execute with no errors.

```
#include <iostream>
using namespace std;
class One {
public:
          void f1() { f3(); cout << "One::f1" << endl; }</pre>
 virtual void f2() { cout << "One::f2" << endl; }</pre>
          void f3() { cout << "One::f3" << endl; }</pre>
};
class Two: public One {
public:
          void f4() { cout << "Two::f4" << endl; }</pre>
          void f2() { f1(); cout << "Two::f2" << endl; }</pre>
 virtual void f3() { f4(); cout << "Two::f3" << endl; }</pre>
};
class Three: public Two {
public:
 void f3() { f2(); cout << "Three::f3" << endl; }</pre>
 void f1() { cout << "Three::f1" << endl; }</pre>
public:
};
int main() {
 return 0;
}
```

Remove this page from the exam, then answer questions about this code on the next pages. **Do not write anything on this page.** It will not be scanned for grading.

### CSE 333 Final Exam December 13, 2017 Sample Solution

**Question 3.** (cont.) (a) (6 points) Complete the diagram below to show the layout of the virtual function tables for the classes given on the previous page. Be sure that the order of pointers in the virtual function tables is clear (i.e., which one is first, then next, etc.). One of the function pointers is already included to help you get started.

(b) (10 points) Now, for each of the following sequences of code, assume that we try to run the program with the given lines of code replacing the empty box in main. Either write the output that is produced when that program is executed, or, if an error occurs, give a concise description of the problem.

(i)	One *x = new Two(); x->fl();	One::f3 One::f1
(ii)	One *x = new Two(); x->f3();	One::f3
(iii)	Two *x = new Two(); x->f3();	Two::f4 Two::f3
(iv)	One *x = new Three(); x->f4();	Compile error: no f4 in class One
(v)	<pre>Three *x = new Three(); x-&gt;f3();</pre>	One::f3 One::f1 Two::f2 Three::f3

(continued on next page)

### CSE 333 Final Exam December 13, 2017 Sample Solution

Question 3. (cont.) (c) (6 points) Now, assume that we change the original code by writing the keyword virtual in front of every function declared in classes One, Two, and Three. Complete the vtable diagram below to show the vtable layouts for the three classes with this change. As before, be sure the order of pointers in each vtable is clear.

(d) (10 points) As before, show the output produced after changing all of the member functions in the classes to be virtual and then replacing the empty box in main with each of the following sequences of code. Either write the output that is produced when the program is executed, or, if an error occurs, give a concise description of the problem.

(i)	One *x = new Two(); x->f1();	Two::f4 Two::f3 One::f1
(ii)	One *x = new Two(); x->f3();	Two::f4 Two::f3
(iii)	Two *x = new Two(); x->f3();	Two::f4 Two::f3
(iv)	One *x = new Three(); x->f4();	Compile error: no f4 in class One
(v)	<pre>Three *x = new Three(); x-&gt;f3();</pre>	Three::f1 Two::f2 Three::f3

### CSE 333 <del>Final</del> 2<sup>nd</sup> Midterm Exam August 18, 2017 **Sample Solution**

**Question 4.** (18 points) A bit of concurrency. Here is yet another small program that creates a handful of threads and lets them run concurrently. (Header files and usings omitted to save space, but this does compile and execute without crashing.)

```
const int NUM THREADS = 3;
                        // global var. changed by threads
static int result = 0;
static pthread mutex t lock; // unused variable (for now)
struct t_args { // arguments for one thread:
 int amount; // amount to add to global result
int count; // number of times to add amount to result
};
// Given a t args struct, add amount to result,
// repeated count times.
void *update result(void *arg) {
  struct t args *p arg = (struct t args *) arg;
  for (int i = 0; i < p arg->count; i++) {
   pthread_mutex_lock(&lock); // added for part (c)
   result += p arg->amount;
   pthread_mutex_unlock(&lock); // added for part (c)
  }
 return NULL;
}
int main(int argc, char** argv) {
  struct t args args[NUM THREADS] = {{5, 4}, {20, 6}, {-5, 2}};
 pthread t thrds[NUM THREADS];
 // initialize lock
 pthread mutex init(&lock, NULL); // added for part (c)
 // create threads
  for (int i = 0; i < NUM THREADS; i++) {</pre>
    if (pthread create(&thrds[i], NULL, &update result, &args[i])
                                                          ! = 0) \{
      cerr << "pthread create failed" << endl;</pre>
    }
  }
  // wait for threads to finish
  for (int i = 0; i < NUM THREADS; i++) {</pre>
    if (pthread_join(thrds[i], NULL) != 0) {
     cerr << "pthread join failed" << endl;</pre>
    }
 // destroy mutex (good practice but not required for static
 // mutex variables - only required for dynamic or automatic)
 // print final value of result and exit
 cout << "Total: " << result << endl;</pre>
 return 0;
}
```

(continued on the next page, but leave this page in the exam. You may need to write some changes in the above code.)

### CSE 333 Final 2<sup>nd</sup> Midterm Exam August 18, 2017 Sample Solution

Question 4. (cont) When we run this program it starts three threads, waits for them all to finish, and then prints the final value of the variable result.

(a) (2 points) What value should this program print if the threads do not interfere with each other (i.e., if, for example, the three threads were executed sequentially, one after the other, rather than running concurrently):

Expected value if no interference: 130

(b) (6 points) When the threads run concurrently, what is the possible range of values that the program could print? (i.e., what are the possible final values for variable result?) Give the minimum and maximum possible values. If concurrent execution always produces the same output, just list that value as both the minimum and maximum.

(Hint: to answer this part of the question, it helps to assume that if we execute the program repeatedly, the concurrent thread scheduling will occur in as many different, unpredictable ways as possible.)

Minimum possible value: -10

Maximum possible value: 140

Reason (not required): Since there is no synchronization, any of the updates can be lost if one thread reads the value of result and then another thread writes a new value before the first thread can write its updated value. The second write will replace the first one, and the update from the other thread will be lost.

(c) (10 points) If it is possible for concurrent execution to produce different results, show the minimal changes needed to guarantee that the global variable result has the expected final value that it would have if the threads executed sequentially (i.e., the value given in your answer to part (a)). Your solution should, however, still allow for as much concurrent execution of the different threads as possible. For example, it is not reasonable to rewrite the code so the threads run sequentially, one after the other or otherwise rewrite the existing code so that it is substantially different.

Show your changes by writing them on the code on the previous page.

A lock is needed to to synchronize updates to result. Code changes shown in bold green on the previous page.
